#### Abstract

A linkage $L$ in a graph $G$ is a subgraph each component of which is a path, and it is vital if $V(L)=V(G)$ and there is no other linkage in $G$ joining the same pairs of vertices. We show that, if $G$ has a vital linkage with $p$ components, then $G$ has tree-width bounded above by a function of $p$. This is the major step in the proof of the unproved lemma from Graph Minors XIII, and it has a number of other applications, including a constructive proof of the intertwining conjecture.

## 1 Introduction

A linkage in a graph $G$ is a subgraph every component of which is a path. (All graphs in this paper are finite and undirected, and may have loops or parallel edges. Paths have at least one vertex, and have no "repeated" vertices or edges.) A vertex of $G$ is a terminal of a linkage $L$ in $G$ if $v \in V(L)$ and $v$ has degree $\leq 1$ in $L$. The pattern of a linkage $L$ is the partition of its terminals in which two terminals are in the same block if and only if they belong to the same component of $L$. A linkage is a $p$-linkage if it has $\leq p$ terminals, where $p \geq 0$ is an integer. A linkage $L$ in $G$ is vital if $V(L)=V(G)$, and no linkage in $G$ different from $L$ has the same pattern as $L$.

A tree-decomposition of a graph $G$ is a pair $(T, W)$, where $T$ is a tree and $W=\left(W_{t}: t \in V(T)\right)$ is a family of subgraphs of $G$, satisfying

1. $\bigcup\left(W_{t}: t \in V(T)\right)=G$, and
2. if $t, t^{\prime}, t^{\prime \prime} \in V(T)$ and $t^{\prime}$ lies on the path of $T$ between $t$ and $t^{\prime \prime}$, then $W_{t} \cap W_{t^{\prime \prime}} \subseteq W_{t^{\prime}}$.

It has width $\leq w$ if $\left|V\left(W_{t}\right)\right| \leq w+1$ for every $t \in V(T)$, and $G$ has tree-width $\leq w$ if some treedecomposition has width $\leq w$.

The main objective of this paper is to prove the following.
1.1 For every integer $p \geq 0$ there exists $w \geq 0$ such that every graph with a vital p-linkage has tree-width $\leq w$.

This has a large number of applications. For instance, in section 11 we use it to obtain a constructive proof of the intertwining conjecture, proved non-constructively in [11]. In the next paper of this series we show that it implies theorem (10.2) of [8], which was left unproved in that paper, and which is needed to justify the main algorithm for the $p$ disjoint paths problem described in that paper; and that it also implies, for example, the main theorem of [5].

Despite all these applications, it seems unlikely that such an apparently innocuous statement should need the elaborate proof that we give in this paper; and perhaps (1.1) has an easy proof that we have missed. If $p \leq 5(1.1)$ is indeed easy, and in fact for $p \leq 5$, every graph with a vital $p$-linkage has path-width $\leq p$. (Path-width is defined in the same way as tree-width except that the tree $T$ is required to be a path.) We shall not need this result, and so we omit its proof, but it follows easily by induction from the following.
1.2 If $L$ is a vital 5-linkage in a simple graph $G$, then either some two terminals in different components of $L$ are adjacent in $G$, or some terminal has the same degree in $G$ and in $L$, or $G$ is null.

This raises the question of whether (1.1) is true in general with tree-width replaced by path-width; and indeed it is, as we shall show in section 12.

Our proof of (1.1) is as follows. From a theorem of [8] it follows immediately that every graph with a vital $p$-linkage has no $K_{n}$ minor, where $n \geq \frac{5}{2} p+1$. Consequently we can apply the results of $[9,10]$ concerning the structure of graphs excluding a fixed minor. They "almost" tell us that $G$ has bounded genus. The remainder of the proof falls into two main parts; first we prove it when $G$ really does have bounded genus, and then we fix the gaps implied by "almost".

## 2 Some basic lemmas

In this section we establish some lemmas about vital linkages that we shall need repeatedly. We use $\backslash$ to denote the result of deletion; thus, $G \backslash X$ is the graph obtained from $G$ by deleting $X$.
2.1 If $L$ is a vital $p$-linkage in $G$, and $X \subseteq V(G)$, then $L \backslash X$ is a vital $(p+2|X|)$-linkage in $G \backslash X$.

The proof is clear.
A separation of $G$ is a pair $(A, B)$ of subgraphs of $G$ with union $G$ and with $E(A \cap B)=\emptyset$; its order is $|V(A \cap B)|$.
2.2 If $L$ is a linkage in $G$ with set of terminals $X$, and $(A, B)$ is a separation of $G$, then $L \cap B$ is a linkage in $B$ with set of terminals a subset of $(X \backslash V(A)) \cup V(A \cap B)$.

Again, the proof is clear, as is the proof of the next lemma.
2.3 If $L$ is a linkage in $G$, and $(A, B)$ is a separation of $G$, and $L^{\prime}$ is a linkage in $B$ with the same pattern as $L \cap B$, then $(L \cap A) \cup L^{\prime}$ is a linkage in $G$ with the same pattern as $L$. In particular, if $L$ is a vital linkage in $G$ then $L \cap B$ is a vital linkage in $B$.

We need the operation of "splitting" a vertex of a graph. (For the following to make sense, we regard a graph as a triple consisting of a set of vertices, a set of edges, and an appropriate incidence relation between them.) Let $v$ be a vertex of a graph $G$, and let $\delta_{1}, \delta_{2} \subseteq E(G)$ with $\delta_{1} \cap \delta_{2}=\emptyset$, so
that $\delta_{1} \cup \delta_{2}$ is the set of all edges of $G$ incident with $v$. Take two new elements $v_{1}, v_{2}$, and let $G^{\prime}$ be the graph with vertex set $(V(G) \backslash\{v\}) \cup\left\{v_{1}, v_{2}\right\}$ and edge set $E(G)$, in which an edge $e$ is incident with a vertex $u \in V\left(G^{\prime}\right)$ if either $u \neq v_{1}, v_{2}$ and $e$ is incident with $u$ in $G$, or $u=v_{i}$ and $e \in \delta_{i}$ for $i=1$ or 2 . We say that $G^{\prime}$ is obtained from $G$ by splitting $v$ (according to $\delta_{1}, \delta_{2}$ ).
2.4 If $G^{\prime}$ is obtained from $G$ by splitting a vertex $v$, and $G$ has a vital p-linkage, then $G^{\prime}$ has a vital $(p+2)$-linkage .

Proof. Let $L$ be a vital $p$-linkage in $G$. Let $L^{\prime}$ be the subgraph of $G^{\prime}$ with $V\left(L^{\prime}\right)=V\left(G^{\prime}\right)$ and $E\left(L^{\prime}\right)=E(L)$. Then $L^{\prime}$ is a vital $(p+2)$-linkage as is easily seen.

If $A, B$ are graphs, we write $A \subseteq B$ to denote that $A$ is a subgraph of $B$.
2.5 Let $p, k \geq 0$ and let $n=(2 p+1)(p+k+1)^{2(p+k)}+1$. Let $L$ be a vital p-linkage in a graph $G$, and for $1 \leq i \leq n$ let $\left(A_{i}, B_{i}\right)$ be a separation of $G$ of order $k$, such that

1. $A_{i} \subseteq A_{j}$ and $B_{j} \subseteq B_{i}$ for $1 \leq i<j \leq n$, and
2. for $1 \leq i<n$, there is a linkage $M_{i}$ in $B_{i} \cap A_{i+1}$ with $k$ components, each with one end in $V\left(A_{i} \cap B_{i}\right)$ and the other in $V\left(A_{i+1} \cap B_{i+1}\right)$.

Then there exists $i$ with $1 \leq i<n$ such that $L \cap B_{i} \cap A_{i+1}=M_{i}$.

Proof. Let $Z$ be the set of terminals of $L$.
(1) At most $2 p+1$ of the pairs $\left(V\left(A_{i}\right) \cap Z, V\left(B_{i}\right) \cap Z\right)(1 \leq i \leq n)$ are distinct.

Subproof. Let $c_{i}=\left|V\left(A_{i}\right) \cap Z\right|-\left|V\left(B_{i}\right) \cap Z\right|(1 \leq i \leq n)$. Then $-p \leq c_{i} \leq p$, and so at most $2 p+1$ of the integers $c_{i}(1 \leq i \leq n)$ are mutually distinct. But if $i<j$, then $V\left(A_{i}\right) \cap Z \subseteq V\left(A_{j}\right) \cap Z$ and $V\left(B_{i}\right) \cap Z \supseteq V\left(B_{j}\right) \cap Z$, and so if $c_{i}=c_{j}$ then

$$
\left(V\left(A_{i}\right) \cap Z, V\left(B_{i}\right) \cap Z\right)=\left(V\left(A_{j}\right) \cap Z, V\left(B_{j}\right) \cap Z\right)
$$

as required. This proves (1).
For $1 \leq i \leq n$, let $V\left(A_{i} \cap B_{i}\right)=\left\{v_{i}^{1}, \ldots, v_{i}^{k}\right\}$, numbered so that for $1 \leq i<n$, the pattern of $M_{i}$ is $\left\{\left\{v_{i}^{1}, v_{i+1}^{1}\right\}, \ldots,\left\{v_{i}^{k}, v_{i+1}^{k}\right\}\right\}$. Let $Z_{i}=V\left(A_{i} \cap B_{i}\right) \cup\left(Z \cap V\left(B_{i}\right)\right)$, and let $L_{i}=L \cap B_{i}$. By (2.2),
$Z_{i}$ contains every terminal of $L_{i}$. Let $\pi_{i}$ be the pattern of $L_{i}$, and let $\phi_{i}: Z_{i} \rightarrow Z_{1}$ be defined by $\phi_{i}\left(v_{i}^{t}\right)=v_{1}^{t}(1 \leq t \leq k)$, and $\phi_{i}(z)=z$ for all $z \in Z_{i} \backslash V\left(A_{i} \cap B_{i}\right)$. Now $\phi_{i}$ is an injection, and maps $\pi_{i}$ to a partition of a subset of $Z_{1}$ in which each block has cardinality 1 or 2 . Since $\left|Z_{1}\right| \leq p+k$, there are at most $(p+k+1)^{2(p+k)}$ such partitions. Since $n>(2 p+1)(p+k+1)^{2(p+k)}$, it follows that there exist distinct $i, j$ with $1 \leq i, j \leq n$, such that $V\left(A_{i}\right) \cap Z=V\left(A_{j}\right) \cap Z, V\left(B_{i}\right) \cap Z=V\left(B_{j}\right) \cap Z$, and $\phi_{i}\left(\pi_{i}\right)=\phi_{j}\left(\pi_{j}\right)$.
(2) For $1 \leq t \leq k$, the degree of $v_{i}^{t}$ in $L_{i}$ equals the degree of $v_{j}^{t}$ in $L_{j}$; and if one of $v_{i}^{t}, v_{j}^{t}$ is in $Z$ then $v_{i}^{t}=v_{j}^{t}$.

Subproof. For the first claim, we observe that $v_{i}^{t}$ has degree 0,1 or 2 in $L_{i}$, depending where $\left\{v_{i}^{t}\right\}$ is a block of $\pi_{i}$, a proper subset of a block of $\pi_{i}$, or not a subset of any block of $\pi_{i}$ respectively. Since $\phi_{i}\left(v_{i}^{t}\right)=\phi_{j}\left(v_{j}^{t}\right)$ and $\phi_{i}\left(\pi_{i}\right)=\phi_{j}\left(\pi_{j}\right)$, the first claim follows. For the second, suppose that $v_{i}^{t} \in Z$. Since $V\left(A_{i}\right) \cap Z=V\left(A_{j}\right) \cap Z$ it follows that $v_{i}^{t} \in V\left(A_{j}\right)$ and similarly $v_{i}^{t} \in V\left(B_{j}\right)$. Thus $v_{i}^{t}=v_{j}^{t^{\prime}}$ for some $t^{\prime}$. Now $M_{1} \cup \ldots \cup M_{n-1}$ is a linkage with $k$ components, and one of them meets $V\left(A_{i} \cap B_{i}\right)$ in $\left\{v_{i}^{t}\right\}$ and meets $V\left(A_{j} \cap B_{j}\right)$ only in $\left\{v_{j}^{t}\right\}$. Since $v_{i}^{t}=v_{j}^{t^{\prime}} \in V\left(A_{j} \cap B_{j}\right)$ it follows that $t^{\prime}=t$. This proves (2).

We may assume that $i<j$. Let $M=M_{i} \cup M_{i+1} \cup \ldots \cup M_{j-1}$, and let the components of $M$ be $P^{1}, \ldots, P^{k}$, where $P^{t}$ has ends $v_{i}^{t}$ and $v_{j}^{t}(1 \leq t \leq k)$. Let

$$
T=\left\{t: 1 \leq t \leq k, \text { and either } v_{i}^{t}=v_{j}^{t} \text { or } v_{i}^{t} \text { has degree } 1 \text { in } L_{i}\right\} .
$$

Let $M^{*}$ be the subgraph of $G$ formed by the vertices in $V\left(A_{i} \cap B_{i}\right)$, the vertices in $V\left(A_{j} \cap B_{j}\right)$, and all the paths $P_{t}(t \in T)$.
(3) $M^{*} \cup L_{j}$ is a linkage in $B_{i}$.

Subproof. It is clearly a forest, and so it suffices to show that it has maximum degree at most 2. Let $v \in V\left(M^{*} \cup L_{j}\right)$. Since $M^{*}$ and $L_{j}$ both have maximum degree $\leq 2$, we may assume that $v \in V\left(M^{*} \cap L_{j}\right)$, and $v$ has degree $\geq 1$ in both $M^{*}$ and $L_{j}$. Hence $v \in V\left(A_{j} \cap B_{j}\right)$, and so $v$ has degree 1 in $M^{*}$ and 1 in $L_{j}$, from the definition of $M^{*}$. This proves (3).
(4) If $P$ is a component of $L_{i}$ with ends $a$ and $b$, then there is a component of $M^{*} \cup L_{j}$ with
ends $a$ and $b$.

Subproof. Since $a$ is a terminal of $L_{i}$, it follows that $a \in V\left(A_{i} \cap B_{i}\right) \cup\left(Z \backslash V\left(A_{i}\right)\right)$, by (2.2). Since $Z \cap V\left(A_{i}\right)=Z \cap V\left(A_{j}\right)$ it follows that if $a \notin V\left(A_{i} \cap B_{i}\right)$ then $a \in Z \backslash V\left(A_{j}\right)$. Similarly, either $b \in V\left(A_{i} \cap B_{i}\right)$ or $b \in Z \backslash V\left(A_{j}\right)$. If $a \in Z \backslash V\left(A_{j}\right)$ let $a^{\prime}=a$, and if $a \in V\left(A_{i} \cap B_{i}\right), a=v_{i}^{t}$ say, let $a^{\prime}=v_{j}^{t}$. Thus $\phi_{j}\left(a^{\prime}\right)=\phi_{i}(a)$. Define $b^{\prime}$ similarly. Now since $\phi_{j}\left(\pi_{j}\right)=\phi_{i}\left(\pi_{i}\right)$ and $\phi_{i}, \phi_{j}$ are injections, and $\{a, b\}$ is a block of $\pi_{i}$, it follows that $\left\{a^{\prime}, b^{\prime}\right\}$ is a block of $\pi_{j}$, that is, there is a component $P^{\prime}$ of $L_{j}$ with ends $a^{\prime}, b^{\prime}$. There are five cases:

Case 1: $a, b \in Z \backslash V\left(A_{j}\right)$.
Then $a=a^{\prime}$ and $b=b^{\prime}$. Now no internal vertex of $P^{\prime}$ has degree $\geq 1$ in $M^{*}$, and $a, b \notin V\left(M^{*}\right)$, and so $P^{\prime}$ is a component of $M^{*} \cup L_{j}$ satisfying (4).

Case 2: $V\left(A_{i} \cap B_{i}\right)$ contains exactly one of $a$, b, say $a$.
Then $a \neq b$, and so $a^{\prime} \neq b^{\prime}=b$. Let $a=v_{i}^{t}$ say; then $a^{\prime}=v_{j}^{t}$, and $v_{j}^{t}$ has degree 1 in $L_{j}$ since it is an end of $P^{\prime}$ and $E\left(P^{\prime}\right) \neq \emptyset$. Consequently $t \in T$, and so $P_{t} \cup P^{\prime}$ is a component of $M^{*} \cup L_{j}$ with ends $a$ and $b$, as required.

Case 3: $a \neq b$, and $a, b \in V\left(A_{i} \cap B_{i}\right)$.
Then again $a^{\prime} \neq b^{\prime}$. Let $a=v_{i}^{s}, b=v_{i}^{t}$; then $a^{\prime}=v_{j}^{s}, b^{\prime}=v_{j}^{t}$. Since $a^{\prime}$ and $b^{\prime}$ both have degree 1 in $L_{j}$ it follows that $s, t \in T$, and so $P_{s} \cup P_{t} \cup P^{\prime}$ is a component of $M^{*} \cup L_{j}$ with ends $a$ and $b$.

Case 4: $a=b \in V\left(A_{i} \cap B_{i}\right)$ and $a=a^{\prime}$.
Let $a=b=v_{i}^{t}$. Then $v_{i}^{t}=a=a^{\prime}=v_{j}^{t}$, and so $a$ has degree 0 in $M^{*}$. Moreover, since $v_{i}^{t}$ has degree 0 in $L_{i}$ (because $|V(P)|=1$ ) it follows from (2) that $v_{j}^{t}$ has degree 0 in $L_{j}$. Hence $a=v_{j}^{t}$ has degree 0 in $M^{*} \cup L_{j}$, and so $P$ is a component of $M^{*} \cup L_{j}$ with ends $a$ and $b$.

Case 5: $a=b \in V\left(A_{i} \cap B_{i}\right)$ and $a \neq a^{\prime}$.
Let $a=b=v_{i}^{t}$; then $a^{\prime}=v_{j}^{t} \neq v_{i}^{t}$. Since $v_{i}^{t}$ has degree 0 in $L_{i}$, it follows that $t \notin T$, and so $a$ has degree 0 in $M^{*}$. Since $a \notin V\left(L_{j}\right)$ we deduce that $a$ has degree 0 in $M^{*} \cup L_{j}$, and so again $P$ is a component of $M^{*} \cup L_{j}$ with ends $a$ and $b$.

In each case we have found a component of $M^{*} \cup L_{j}$ with ends $a$ and $b$. This proves (4).
(5) $L \subseteq\left(L \cap A_{i}\right) \cup M^{*} \cup L_{j}$.

Subproof. (4) implies that there is a linkage in $M^{*} \cup L_{j}$ with the same pattern as $L_{i}$. From (2.3), it follows that there is a linkage in $\left(L \cap A_{i}\right) \cup M^{*} \cup L_{j}$ with the same pattern as $L$. Since $L$ is vital, we deduce that $L \subseteq\left(L \cap A_{i}\right) \cup M^{*} \cup L_{j}$. This proves (5).
(6) $T=\{1, \ldots, k\}$.

Subproof. Suppose that $1 \leq t \leq k$ and $t \notin T$. Then $v_{i}^{t} \neq v_{j}^{t}$, and $v_{i}^{t}$ has degree 0 or 2 in $L_{i}$. Suppose first that $v_{i}^{t}$ has degree 0 in $L_{i}$. Then $v_{j}^{t}$ has degree 0 in $L_{j}$ by (2), it has degree 0 in $M^{*}$ since $t \notin T$, and is not a vertex of $L \cap A_{i}$. Consequently, $v_{j}^{t}$ has degree 0 in $\left(L \cap A_{i}\right) \cup M^{*} \cup L_{j}$. Since $V(L) \backslash V(G)$, it follows from (5) that $v_{j}^{t}$ has degree 0 in $L$, and so $v_{j}^{t} \in Z$, contrary to (2) since $v_{i}^{t} \neq v_{j}^{t}$. It follows that $v_{i}^{t}$ does not have degree 0 in $L_{i}$. Now $v_{i}^{t}$ has degree $\leq 1$ in $M^{*}$ and is not a vertex of $L_{j}$, since $v_{i}^{t} \neq v_{j}^{t}$. Consequently, $v_{i}^{t}$ has degree $\leq 1$ in $M^{*} \cup L_{j}$. But from (5), $L_{i} \subseteq M^{*} \cup L_{j}$, and hence $v_{i}^{t}$ has degree $\leq 1$ in $L_{i}$, and hence $t \in T$, a contradiction. This proves (6).

From (6) it follows that $M^{*}=M$.
(7) $M$ is a subgraph of $L$.

Subproof. Let $1 \leq t \leq k$; we claim that $P^{t}$ is a subgraph of $L$. If $v_{i}^{t}=v_{j}^{t}$ this is clear, and so we may assume that $v_{i}^{t} \neq v_{j}^{t}$. By (2), $v_{i}^{t}, v_{j}^{t} \notin Z$. Moreover, since $V\left(A_{i}\right) \cap Z=V\left(A_{j}\right) \cap Z$ and the internal vertices of $P^{t}$ belong to $V\left(A_{j}\right) \backslash V\left(A_{i}\right)$, it follows that no vertex of $P_{t}$ is a terminal of $L$, and so they all have degree 2 in $L$. From (6), $v_{j}^{t}$ has degree 1 in $L_{j}$, but it has degree 2 in $L$, and so $L$ contains the edge of $P^{t}$ incident with $v_{j}^{t}$. From (5) it follows that $L$ contains both edges of $P^{t}$ incident with any internal vertex of $P^{t}$. Consequently $E\left(P^{t}\right) \subseteq E(L)$. This proves (7).

From (5) and (7), $L \cap B_{j} \cap A_{i} \subseteq M^{*}=M \subseteq L \cap B_{j} \cap A_{i}$. Consequently, $L \cap B_{j} \cap A_{i}=M$, and so $L \cap B_{i+1} \cap A_{i}=M_{i}$, as required.

Here is a slight strengthening of (2.5).
2.6 For all integers $p, k \geq 0$ there exists $n \geq 0$ with the following property. Let $L$ be a vital $p$-linkage in a graph $G$, and for $1 \leq i \leq n$ let $\left(A_{i}, B_{i}\right)$ be a separation of $G$ of order $\leq k$, such that

1. $A_{i} \subseteq A_{j}$ and $B_{j} \subseteq B_{i}$, for $1 \leq i<j \leq n$
2. if $1 \leq i<i^{\prime} \leq n$, and $\left|V\left(A_{i} \cap B_{i}\right)\right|=\left|V\left(A_{i^{\prime}} \cap B_{i^{\prime}}\right)\right|=k^{\prime}$ say, and $\left|V\left(A_{j} \cap B_{j}\right)\right|>k^{\prime}$ for all $j$ with $i<j<i^{\prime}$, then there is a linkage $M_{i i^{\prime}}$ in $B_{i} \cap A_{i^{\prime}}$ with $k^{\prime}$ components, each with one end in $V\left(A_{i} \cap B_{i}\right)$ and the other in $V\left(A_{i^{\prime}} \cap B_{i^{\prime}}\right)$.

Then there exist $i, i^{\prime}$ as in (ii) such that $L \cap B_{i} \cap A_{i^{\prime}}=M_{i i^{\prime}}$.
Proof. For $0 \leq k^{\prime} \leq k$ let $n\left(k^{\prime}\right)=(2 p+1)\left(p+k^{\prime}+1\right)^{2\left(p+k^{\prime}\right)}+1$, and for $0 \leq k^{\prime} \leq k$ let

$$
m\left(k^{\prime}\right)=n(0) n(1) n(2) \ldots n\left(k^{\prime}\right)
$$

Let $n=m(k)$; we shall show it satisfies the theorem. For let $G, L$ and $\left(A_{i}, B_{i}\right)(1 \leq i \leq n)$ and the $M_{i i^{\prime}}$ be as in the theorem. Since there are at least $m(k)$ values of $i$ with $1 \leq i \leq n$ such that $\left|V\left(A_{i} \cap B_{i}\right)\right| \leq k$, there exists $k^{\prime} \leq k$ minimum such that

$$
\left|\left\{i: 1 \leq i \leq n,\left|V\left(A_{i} \cap B_{i}\right)\right| \leq k^{\prime}\right\}\right| \geq m\left(k^{\prime}\right) .
$$

If $k^{\prime}=0$, then from (2.5) (with $k$ replaced by 0 ) applied to the sequence of all $\left(A_{i}, B_{i}\right)$ of order 0 , we find the desired $M_{i i^{\prime}}$, as required. We assume then that $k^{\prime}>0$. From the minimality of $k^{\prime}$, it follows that

$$
\left|\left\{i: 1 \leq i \leq n,\left|V\left(A_{i} \cap B_{i}\right)\right| \leq k^{\prime}-1\right\}\right| \leq m\left(k^{\prime}-1\right)-1,
$$

and so

$$
\left|\left\{i: 1 \leq i \leq n,\left|V\left(A_{i} \cap B_{i}\right)\right| \leq k^{\prime}\right\}\right| \geq n\left(k^{\prime}\right)\left(\left|\left\{i: 1 \leq i \leq n,\left|V\left(A_{i} \cap B_{i}\right)\right| \leq k^{\prime}-1\right\}\right|+1\right) .
$$

By examining the intervals between consecutive members of the second set, it follows that there exist $i_{1}, i_{2}$ with $1 \leq i_{1}<i_{2} \leq n$, such that

$$
\begin{aligned}
& \left|\left\{i: i_{1} \leq i \leq i_{2},\left|V\left(A_{i} \cap B_{i}\right)\right|=k^{\prime}\right\}\right| \geq n\left(k^{\prime}\right) \\
& \left\{i: i_{1} \leq i \leq i_{2},\left|V\left(A_{i} \cap B_{i}\right)\right|<k^{\prime}\right\}=\emptyset .
\end{aligned}
$$

Then the result follows, from (2.5) applied to the sequence $\left(A_{i}, B_{i}\right)\left(i_{1} \leq i \leq i_{2},\left|V\left(A_{i} \cap B_{i}\right)\right|=\right.$ $\left.k^{\prime}\right)$.

Similarly, we have
2.7 For all integers $p, k \geq 0$ there exists $n \geq 0$ with the following property. Let $L, L^{\prime}$ be vital $p$ linkages in a graph $G$, and for $1 \leq i \leq n$ let $\left(A_{i}, B_{i}\right)$ be as in (2.6), satisfying (2.6)(i) and (ii). Then there exist $i, i^{\prime}$ as in (ii) such that $L \cap B_{i} \cap A_{i^{\prime}}=L^{\prime} \cap B_{i} \cap A_{i^{\prime}}=M_{i i^{\prime}}$.

Proof. First we prove an analogous version of (2.5) for two linkages $L, L^{\prime}$ instead of one. We let $Z$ be the terminals of either $L$ or $L^{\prime}$, and then follow the proof of (2.5), taking

$$
n=(4 p+1)(2 p+k+1)^{2(2 p+k)}+1 .
$$

Statement (1) in the proof of (2.5) holds with $2 p+1$ replaced by $4 p+1$, since $|Z| \leq 2 p$. We find distinct $i, j$ with $1 \leq i, j \leq n$ such that $V\left(A_{i}\right) \cap Z=V\left(A_{j}\right) \cap Z, V\left(B_{i}\right) \cap Z=V\left(B_{j}\right) \cap Z, \phi_{i}\left(\pi_{i}\right)=$ $\phi_{j}\left(\pi_{j}\right)$, and $\phi_{i}\left(\pi_{i}^{\prime}\right)=\phi_{j}\left(\pi_{j}^{\prime}\right)$, where $\pi_{i}^{\prime}$ is the pattern of $L^{\prime} \cap B_{i}$. Then the proof of (2.5) yields that $L \cap B_{i} \cap A_{i+1}=M_{i}$ and $L^{\prime} \cap B_{i} \cap A_{i+1}=M_{i}$, as required.

Now we use this modified version of (2.5) to prove (2.7), by modifying the proof of (2.6) in the obvious way.

## 3 Tangles

A tangle of order $\theta \geq 1$ in a graph $G$ is a set $\mathcal{T}$ of separations of $G$, all of order $<\theta$, such that
(i) one of $(A, B),(B, A)$ belongs to $\mathcal{T}$, for every separation $(A, B)$ of $G$ of order $<\theta$
(ii) if $\left(A_{i}, B_{i}\right) \in \mathcal{T}(1 \leq i \leq 3)$ then $A_{1} \cup A_{2} \cup A_{3} \neq G$
(iii) if $(A, B) \in \mathcal{T}$ then $V(A) \neq V(G)$.

We write $\operatorname{ord}(\mathcal{T})=\theta$. Tangles were introduced in [6]. We shall need several lemmas about tangles, which we establish in this section. First, the following was shown in theorem (5.2) of [6].
3.1 If a graph $G$ has tree-width $w$, then $G$ has a tangle of order $\geq \frac{2}{3}(w+1)$, and has no tangle of order $>w+1$.

If $\mathcal{T}$ is a tangle of order $\theta$ in a graph $G$, and $W \subseteq V(G)$ with $|W|<\theta$, we denote

$$
\{(A \backslash W, B \backslash W):(A, B) \in \mathcal{T}, W \subseteq V(A \cap B)\}
$$

by $\mathcal{T} \backslash W$. The following is theorem (8.5) of [6].
3.2 With $\mathcal{T}, \theta, G, W$ as above, $\mathcal{T} \backslash W$ is a tangle of order $\theta-|W|$ in $G \backslash W$.
[13, theorem (2.9)] asserts
3.3 Let $\mathcal{T}$ be a tangle in a graph $G$, and let $(C, D) \in \mathcal{T}$ of order 0 . Let

$$
\mathcal{T}^{\prime}=\{(A \cap D, B \cap D):(A, B) \in \mathcal{T}\}
$$

Then $\mathcal{T}^{\prime}$ is a tangle in $B$ of the same order as $\mathcal{T}$.
From [13, theorem (2.3)] or theorem (6.1) of [6] we have
3.4 Let $G^{\prime}$ be a subgraph of $G$, and let $\mathcal{T}^{\prime}$ be a tangle in $G^{\prime}$. Let $\mathcal{T}$ be the set of all separations $(A, B)$ of $G$ of order $<\operatorname{ord}\left(\mathcal{T}^{\prime}\right)$ such that $\left(A \cap G^{\prime}, B \cap G^{\prime}\right) \in \mathcal{T}^{\prime}$. Then $\mathcal{T}$ is a tangle in $G$ of order $\operatorname{ord}\left(\mathcal{T}^{\prime}\right)$.

We also need the following.
3.5 Let $\mathcal{T}$ be a tangle in $G$ and let $\left(A_{0}, B_{0}\right) \in \mathcal{T}$. Then there is a tangle $\mathcal{T}_{0}$ in $B_{0}$ of order $\operatorname{ord}(\mathcal{T})-$ $\left|V\left(A_{0} \cap B_{0}\right)\right|$, such that $\left(A \cap B_{0}, B \cap B_{0}\right) \in \mathcal{T}_{0}$ for every $(A, B) \in \mathcal{T}$ of order $<\operatorname{ord}(\mathcal{T})-\left|V\left(A_{0} \cap B_{0}\right)\right|$.

Proof. Let $\operatorname{or} d(\mathcal{T})=\theta$, and let $V\left(A_{0} \cap B_{0}\right)=W$, where $|W|<\theta$. Then $\mathcal{T} \backslash W$ is a tangle in $G \backslash W$ of order $\theta-|W|$, by (3.2), and $\left(A_{0} \backslash W, B_{0} \backslash W\right) \in \mathcal{T} \backslash W$, and has order 0 . Let

$$
\mathcal{T}_{1}=\left\{\left(A \cap\left(B_{0} \backslash W\right), B \cap\left(B_{0} \backslash W\right):(A, B) \in \mathcal{T} \backslash W\right\}\right.
$$

By [13, theorem (2.9)], $\mathcal{I}_{1}$ is a tangle in $B_{0} \backslash W$ of order $\theta-|W|$. Let $\mathcal{T}_{0}$ be the tangle of order $\theta-|W|$ in $B_{0}$ induced by $\mathcal{I}_{1}$; this exists, by (3.4). We claim that $\mathcal{T}_{0}$ satisfies the theorem.

For let $(A, B) \in \mathcal{T}$ with order $<\theta-|W|$. Let $A^{\prime}$ be the subgraph of $G$ with $E\left(A^{\prime}\right)=E(A)$ and $V\left(A^{\prime}\right)=V(A) \cup W$, and define $B^{\prime}$ similarly. Then $\left(A^{\prime}, B^{\prime}\right)$ has order $<\theta$, and so $\left(A^{\prime}, B^{\prime}\right) \in \mathcal{T}$, by theorem (2.9) of [6]. Consequently, $\left(A^{\prime} \backslash W, B^{\prime} \backslash W\right) \in \mathcal{T} \backslash W$. From the definition of $\mathcal{T}_{1}$,

$$
\left(\left(A^{\prime} \backslash W\right) \cap\left(B_{0} \backslash W\right),\left(B^{\prime} \backslash W\right) \cap\left(B_{0} \backslash W\right)\right) \in \mathcal{T}_{1}
$$

But $\left(A^{\prime} \backslash W\right) \cap\left(B_{0} \backslash W\right)=\left(A \cap B_{0}\right) \backslash W$, and $\left(B^{\prime} \backslash W\right) \cap\left(B_{0} \backslash W\right)=\left(B \cap B_{0}\right) \backslash W$, and so $\left(\left(A \cap B_{0}\right) \backslash W,\left(B \cap B_{0}\right) \backslash W\right) \in \mathcal{T}_{1}$, that is,

$$
\left(\left(A \cap B_{0}\right) \cap\left(B_{0} \backslash W\right),\left(B \cap B_{0}\right) \cap\left(B_{0} \backslash W\right)\right) \in \mathcal{T}_{1}
$$

Since $\left(A \cap B_{0}, B \cap B_{0}\right)$ is a separation of $B_{0}$ of order $<\theta-|W|$, we deduce from the definition of $\mathcal{T}_{0}$ that $\left(A \cap B_{0}, B \cap B_{0}\right) \in \mathcal{T}_{0}$, as required.
3.6 If $G^{\prime}$ can be obtained from $G$ by splitting a vertex, and $\mathcal{T}$ is a tangle in $G$ of order $\geq 2$, there is a tangle in $G^{\prime}$ of order $\operatorname{ord}(\mathcal{T})-1$.

Proof. Let $G^{\prime}$ be obtained by splitting $v \in V(G)$. By (3.2), $G \backslash v$ has a tangle of order $\operatorname{ord}(\mathcal{T})-1$, and hence by (3.4), so does $G^{\prime}$, since $G \backslash v$ is a subgraph of $G^{\prime}$.

Let us mention also the obvious
3.7 If $\mathcal{T}$ is a tangle in $G$, and $\theta$ is an integer with $1 \leq \theta \leq \operatorname{ord}(\mathcal{T})$, then the set of all members of $\mathcal{T}$ of order $<\theta$ is a tangle in $G$ of order $\theta$.

We call this tangle the $\theta$-truncation of $\mathcal{T}$.

## 4 Surfaces

A surface is a connected compact 2-manifold, possibly with boundary. The boundary of a surface $\Sigma$ is denoted by $b d(\Sigma)$. The components of $b d(\Sigma)$ are called the cuffs of $\Sigma$; each cuff is homeomorphic to a circle. An 0-arc in $\Sigma$ is a subset homeomorphic to a circle, and a line is a subset homeomorphic to the closed interval $[0,1]$. The ends of a line are defined in the natural way. If $X \subseteq \Sigma$, its topological closure is denoted by $\bar{X}$. The surface obtained from $\Sigma$ by pasting a closed disc onto every cuff is denoted by $\hat{\Sigma}$.

If $\Sigma_{1}$ and $\Sigma_{2}$ are surfaces with null boundary, we say that $\Sigma_{1}$ is simpler than $\Sigma_{2}$ if $\Sigma_{2}$ can be obtained from $\Sigma_{1}$ by adding handles or crosscaps (at least one). For a general surface $\Sigma$ we denote the number of cuffs of $\Sigma$ by $c(\Sigma)$. In this paper we shall prove several different statements about surfaces $\Sigma$ by a double induction; we assume that the statement is true for all surfaces $\Sigma^{\prime}$ with $\hat{\Sigma}^{\prime}$ simpler than $\hat{\Sigma}$, and we assume it is true for all $\Sigma^{\prime}$ with $\hat{\Sigma}^{\prime}$ homeomorphic to $\hat{\Sigma}$ and with $c\left(\Sigma^{\prime}\right)<c(\Sigma)$.

To accomplish this, we shall need to consider cutting surfaces along certain lines and 0 -arcs. A line in $\Sigma$ is proper if its ends are in $b d(\Sigma)$ and it has no internal point in $b d(\Sigma)$. The operations we need are: cutting along a proper line, and cutting a surface with null boundary along an $O$-arc. In both cases we shall only use the operation when it results in another (connected) surface. What we mean by these operations is clear, but the notation is a little tricky. To simplify matters as far as possible, we postulate that cutting along a line or $O-\operatorname{arc} F$ in $\Sigma$ as described above results in another surface $\Sigma^{\prime}$ with $\Sigma \cap \Sigma^{\prime}=\Sigma \backslash F$, such that for every point of $F$ there correspond two points of $\Sigma^{\prime} \backslash \Sigma$, both in $b d\left(\Sigma^{\prime}\right)$, in the natural way. We observe:
4.1 Let $\Sigma$ be a surface, and let $\Sigma^{\prime}$ be obtained by cutting along $F \subseteq \Sigma$.

1. If $F$ is a proper line with ends in different cuffs then $\hat{\Sigma}^{\prime}$ is homeomorphic to $\hat{\Sigma}$ and $c\left(\hat{\Sigma}^{\prime}\right)=$ $c(\hat{\Sigma})-1$.
2. If $F$ is a proper line with ends in the same cuff and $\Sigma^{\prime}$ is connected then $\hat{\Sigma}^{\prime}$ is simpler than $\hat{\Sigma}$.
3. If $b d(\Sigma)=\emptyset$ and $F$ is an $O$-arc and $\Sigma^{\prime}$ is connected then $\hat{\Sigma}^{\prime}$ is simpler than $\Sigma$.

The proof is straightforward, and we omit it. We shall also have to deal with line and $O$-arcs $F$ which separate $\Sigma$ (that is, such that $\Sigma \backslash F$ is disconnected), but in these cases there are surfaces $\Sigma_{1}, \Sigma_{2} \subseteq \Sigma$ with $\Sigma_{1} \cup \Sigma_{2}=\Sigma$ and $\Sigma_{1} \cap \Sigma_{2}=F$, and we can get away with using these subsurfaces. In these cases, therefore, no cutting is needed, which is convenient for purposes of notation. The corresponding results are:
4.2 Let $\Sigma$ be a surface, and let $\Sigma_{1}, \Sigma_{2} \subseteq \Sigma$ be surfaces with $\Sigma_{1} \cup \Sigma_{2}=\Sigma$ and $\Sigma_{1} \cap \Sigma_{2}=F$.

1. If $F$ is a proper line in $\Sigma$ with both ends in the same cuff, then either $\hat{\Sigma}_{2}$ is simpler than $\hat{\Sigma}$ or $\hat{\Sigma}_{1}$ is a sphere.
2. If $F$ is a proper line in $\Sigma$ with both ends in the same cuff, and $\hat{\Sigma}_{1}$ is a sphere, then $\hat{\Sigma}_{2}$ is homeomorphic to $\hat{\Sigma}$; and either $c\left(\Sigma_{2}\right)<c(\Sigma)$, or $c\left(\Sigma_{2}\right)=c(\Sigma)$ and there is a closed disc $\Delta \subseteq \Sigma$ with $F \subseteq b d(\Delta) \subseteq F \cup b d(\Sigma)$.
3. If $b d(\Sigma)=\emptyset$ and $F$ is an $O$-arc in $\Sigma$, then either $\hat{\Sigma}_{2}$ is simpler than $\hat{\Sigma}$ or $\Sigma_{1}$ is a closed disc.

A drawing in a surface $\Sigma$ is a pair $(U, V)$ where $U \subseteq \Sigma$ is closed, $V \subseteq U$ is finite, $U \cap b d(\Sigma) \subseteq$ $V, U \backslash V$ has only finitely many connected components, called edges, and for each edge $e$, either

1. its closure $\bar{e}$ is an $O$-arc with $|\bar{e} \cap V|=1$, or
2. its closure is a line meeting $V$ in precisely its ends.

If $\Gamma=(U, V)$ is a drawing we write $U(\Gamma)=U$ and $V(\Gamma)=V$. A drawing $\Gamma$ is therefore a graph with vertex set $V(\Gamma)$, and we use graph-theoretic terminology for drawings without further explanation.

If $\Gamma$ is a drawing in $\Sigma$, and $F \subseteq \Sigma$, we say that $F$ is $\Gamma$-normal if $F \cap U(\Gamma) \subseteq V(\Gamma)$. If $F$ is a $\Gamma$-normal $O$-arc or line which does not separate $\Sigma$, and $\Sigma^{\prime}$ is obtained by cutting along $\Sigma$, then
by splitting the vertices of $\Gamma$ which lie in $F$ in the natural way we obtain a new drawing $\Gamma^{\prime}$ in $\Sigma^{\prime}$. Provided that $\Gamma$ is loopless, this definition agrees with the definition of splitting a vertex discussed for general graphs in section 2.

If $b d(\Sigma)=\emptyset$, a drawing $\Gamma$ in $\Sigma$ is 2 -cell if every region of $\Gamma$ in $\Sigma$ is homeomorphic to an open disc. We need the following two well-known lemmas.
4.3 If $\operatorname{bd}(\Sigma)=\emptyset$, a drawing $\Gamma$ in $\Sigma$ is 2-cell if and only if $V(\Gamma) \neq \emptyset, \Gamma$ is connected, and for every $O$-arc $F \subseteq \Sigma$ with $F \cap U(\Gamma)=\emptyset$, there is a closed disc $\Delta \subseteq \Sigma$ with $b d(\Delta)=F$.

Proof. The "only if" direction is obvious. For "if", let $r$ be a region of $\Gamma$ in $\Sigma$. Since $V(\Gamma) \neq \emptyset$ it follows that $r$ is not a sphere. If every $O$-arc $F \subseteq r$ bounds a closed disc in $r$, then $r$ is an open disc by [5, theorem (4.2)]. Suppose that $F \subseteq r$ is an $O$-arc which bounds no closed disc in $r$. From the hypothesis, $F$ bounds a closed disc $\Delta \subseteq \Sigma$, but $\Delta \nsubseteq r$, and so $\Delta \cap V(\Gamma) \neq \emptyset$. Since $F \cap U(\Gamma)=\emptyset$ and $\Gamma$ is connected it follows that $U(\Gamma) \subseteq \Delta$. If $\Sigma$ is not a sphere, there is a non-null-homotopic $O$-arc $F^{\prime} \subseteq \Sigma$, and it can be chosen with $F^{\prime} \cap \Delta=\emptyset$ since $\Delta$ is a disc; but then $F^{\prime} \subseteq r$ contrary to the hypothesis. If $\Sigma$ is a sphere, let $\Delta^{\prime}$ be the disc different from $\Delta$ bounded by $F$; then $\Delta^{\prime} \subseteq r$, contrary to our assumption. In either case we have a contradiction, and so there is no such $F$, as required.

We remind the reader of the following basic fact [1, theorem (1.7)].
4.4 If $\operatorname{bd}(\Sigma)=\emptyset$, an $O$-arc $F \subseteq \Sigma$ bounds a closed disc in $\Sigma$ if and only if $F$ is null-homotopic in $\Sigma$.

Let $\Gamma$ be a drawing in $\Sigma$, and let $\mathcal{T}$ be a tangle in $\Gamma$. We say that $\mathcal{T}$ is respectful if $\Gamma$ is connected and every $\Gamma$-normal $O$-arc $F \subseteq \hat{\Sigma}$ with $|F \cap V(\Gamma)|<\operatorname{ord}(\mathcal{T})$ bounds a disc $\Delta \subseteq \hat{\Sigma}$ such that

$$
(\Gamma \cap \Delta, \Gamma \cap \overline{\hat{\Sigma} \backslash \Delta}) \in \mathcal{T}
$$

(If $\Sigma^{\prime} \subseteq \Sigma$ is a surface, and $b d\left(\Sigma^{\prime}\right)$ is $\Gamma$-normal, we denote the drawing $\left(U(\Gamma) \cap \Sigma^{\prime}, V(\Gamma) \cap \Sigma^{\prime}\right)$ in $\Sigma^{\prime}$ by $\Gamma \cap \Sigma^{\prime}$.) If $\Delta$ is related to $F$ as above we write $\Delta=\operatorname{ins}(F)$. If there is a respectful tangle in a drawing $\Gamma$ in $\Sigma$, then $\Gamma$ is automatically 2 -cell in $\hat{\Sigma}$, by (4.3).

The main result of this section is the following.
4.5 For every surface $\Sigma$ with $b d(\Sigma)=\emptyset$ and every integer $\theta^{\prime} \geq 1$ there is an integer $\theta \geq 1$ such that, if $\Gamma$ is a drawing in $\Sigma$ with a tangle of order $\geq \theta$, and $\Gamma^{\prime}$ is obtained from $\Gamma$ by deleting some vertices and edges, all incident with one region of $\Gamma$ in $\Sigma$, then $\Gamma^{\prime}$ has a tangle of order $\geq \theta^{\prime}$.

Proof. We proceed by induction on $\Sigma$, and assume inductively that the result holds for every surface with null boundary simpler than $\Sigma$. Consequently,
(1) For every $\phi \geq 1$ there exists $f(\phi) \geq \phi$ such that for every surface $\Sigma^{\prime}$ with $b d\left(\Sigma^{\prime}\right)=\emptyset$ simpler than $\Sigma$, if $\Gamma$ is a drawing in $\Sigma^{\prime}$ with a tangle of order $\geq f(\phi)$, and $\Gamma^{\prime}$ is obtained from $\Gamma$ by deleting some vertices and edges, all incident with one region, then $\Gamma^{\prime}$ has a tangle of order $\geq \phi$.

Given $\theta^{\prime} \geq 1$, let $\theta=\theta^{\prime}+6+f\left(f\left(\theta^{\prime}\right)\right)$; we shall show that $\theta$ satisfies the theorem. Let $\Gamma$ be a drawing in $\Sigma$, let $\mathcal{T}$ be a tangle in $\Gamma$ of order $\geq \theta$, let $r$ be a region of $\Gamma$ in $\Sigma$, and let $\Gamma^{\prime}$ be a drawing obtained from $\Gamma$ by deleting some vertices and edges of $\Gamma$ all incident with $r$.

There exists $\left(\Gamma_{1}, \Gamma_{2}\right) \in \mathcal{T}$ of order 0 such that $\Gamma_{2}$ is connected, by theorem (2.8) of [6] applied to the 1-truncation of $\mathcal{T}$. By (3.3) there is a tangle in $\Gamma_{2}$ of order $\geq \theta$, and $\Gamma^{\prime} \cap \Gamma_{2}$ is obtained from $\Gamma_{2}$ by deleting some vertices and edges all on one region of $\Gamma_{2}$ in $\Sigma$. If $\Gamma^{\prime} \cap \Gamma_{2}$ has a tangle of order $\geq \theta^{\prime}$, then so does $\Gamma^{\prime}$ by (3.4). Consequently it suffices to prove the theorem for $\Gamma_{2}$; in other words, we may assume that $\Gamma$ is connected.

Let $\mathcal{T}_{1}$ be the $\left(\theta^{\prime}+6\right)$-truncation of $\mathcal{T}$. If $\mathcal{T}_{1}$ is respectful, then by theorem (7.8) of [7] (with $k=3$ ), there is a tangle in $\Gamma^{\prime}$ of order $\theta^{\prime}$, since $\theta^{\prime}+6 \geq 9$, as required. We may assume therefore that $\mathcal{T}_{1}$ is not respectful. Since $\Gamma$ is connected, we deduce
(2) There is a $\Gamma$-normal $O$-arc $F \subseteq \Sigma$ with $|F \cap V(\Gamma)|<\theta^{\prime}+6$, such that there is no closed disc $\Delta \subseteq \Sigma$ bounded by $F$ with $(\Gamma \cap \Delta, \Gamma \cap \overline{\Sigma \backslash \Delta}) \in \mathcal{T}$.

It follows that $\Sigma$ is not a sphere. There are two cases, depending on whether $F$ separates $\Sigma$ or not. We assume first that it does not. Let $\Sigma^{\prime}$ be obtained from $\Sigma$ by cutting along $F$. Then $\hat{\Sigma}^{\prime}$ is simpler than $\Sigma$ by (4.1)(iii). Let $\Gamma^{\prime \prime}$ be obtained from $\Gamma$ by deleting all vertices in $F \cap V(\Gamma)$. By (3.2), $\Gamma^{\prime \prime}$ has a tangle of order

$$
\operatorname{ord}(\mathcal{T})-|F \cap V(\Gamma)| \geq \theta-\left(\theta^{\prime}+6\right)=f\left(f\left(\theta^{\prime}\right)\right) .
$$

Now $\Gamma^{\prime \prime}$ is a drawing in $\hat{\Sigma}^{\prime}$ and there are one or two regions of $\Gamma^{\prime \prime}$ in $\hat{\Sigma}^{\prime}$, say $r_{1}$ and $r_{2}$ where possibly $r_{1}=r_{2}$, such that $\Gamma^{\prime} \cap \Gamma^{\prime \prime}$ is obtained from $\Gamma^{\prime \prime}$ by deleting some vertices and edges incident with either $r_{1}$ or $r_{2}$. By two applications of (1), we deduce that $\Gamma^{\prime} \cap \Gamma^{\prime \prime}$ has a tangle of order $\geq \theta^{\prime}$, and hence so does $\Gamma^{\prime}$ by (3.4), as required.

In the second case, we assume that $F$ separates $\Sigma$. Let $\Sigma_{1}, \Sigma_{2} \subseteq \Sigma$ be surfaces with $\Sigma_{1} \cup \Sigma_{2}=$ $\Sigma$ and $\Sigma_{1} \cap \Sigma_{2}=F$. Let $\Gamma_{i}=\Gamma \cap \Sigma_{i}(i=1,2)$. Since $\left(\Gamma_{1}, \Gamma_{2}\right)$ is a separation of $\Gamma$ of order $<\theta^{\prime}+6 \leq \operatorname{ord}(\mathcal{T})$ (by (2)) we may assume from the symmetry that $\left(\Gamma_{1}, \Gamma_{2}\right) \in \mathcal{T}$. From (2), $\Sigma_{1}$ is not a disc, and so from (4.2)(iii), $\hat{\Sigma}_{2}$ is simpler that $\Sigma$. From (3.5) there is a tangle in $\Gamma_{2}$ of order $\geq \operatorname{ord}(\mathcal{T})-|F \cap V(\Gamma)| \geq f\left(f\left(\theta^{\prime}\right)\right) \geq f\left(\theta^{\prime}\right)$.

Now $\Gamma_{2} \cap \Gamma^{\prime}$ is obtained from $\Gamma_{2}$ by deleting some vertices and edges all incident with one region of $\Gamma_{2}$ in $\hat{\Sigma}_{2}$, and so from (1), $\Gamma_{2} \cap \Gamma^{\prime}$ has a tangle of order $\geq \theta^{\prime}$. By (3.4), so does $\Gamma^{\prime}$, as required.

By $\rho$ repeated applications of (4.5), we deduce
4.6 For any surface $\Sigma$ with $b d(\Sigma)=\emptyset$, and all integers $\theta^{\prime} \geq 1$ and $\rho \geq 0$, there exists $\theta \geq 1$ such that, if $\Gamma$ is a drawing in $\Sigma$ with a tangle of order $\geq \theta$, and $r_{1}, \ldots, r_{\rho}$ are regions of $\Gamma$ in $\Sigma$, and $\Gamma^{\prime}$ is obtained from $\Gamma$ by deleting some vertices and edges each incident with one of $r_{1}, \ldots, r_{\rho}$, then $\Gamma^{\prime}$ has a tangle of order $\geq \theta^{\prime}$.

## 5 Linkages on surfaces

In this section we prove (1.1) for graphs which can be drawn on a fixed surface. We need some further definitions.

If $C$ is a cuff of $\Sigma$ and $\Gamma$ is a drawing in $\Sigma$, there is a unique region of $\Gamma$ in $\hat{\Sigma}$ which includes $C \backslash V(\Gamma)$, and we call it the cuff region of $\Gamma$ in $\hat{\Sigma}$ corresponding to $C$. An atom of a drawing $\Gamma$ in a surface $\Sigma$ is either a region of $\Gamma$ in $\hat{\Sigma}$, or an edge of $\Gamma$, or a set $\{v\}$ where $v$ is a vertex. The set of atoms is denoted by $A(\Gamma)$, or $A_{\Sigma}(\Gamma)$ in cases of ambiguity. If $\Gamma$ is a drawing in $\Sigma$ and $\mathcal{T}$ is a respectful tangle in $\Gamma$, then, as discussed in $[7], \mathcal{T}$ defines a metric on $A(\Gamma)$, defined as follows. Let $K$ be a drawing in $\Gamma$ such that $V(\Gamma) \subseteq V(K)$, every region of $\Gamma$ includes a unique vertex of $K$, and $U(\Gamma) \cap U(K)=V(\Gamma) \cap V(K)$; and so that for every region $r$ of $\Gamma$, the vertex of $K$ it contains is adjacent in $K$ to every vertex $v$ of $\Gamma$ incident with $r$, by multiple edges if $r$ is incident with $v$ more than once, in the natural sense. For a closed walk $W$ of $K$ of length $<2 \operatorname{ord}(\mathcal{T})$, let $\operatorname{ins}(W)$ be the union of the atoms of $K$ in $W$ together with all sets $\operatorname{ins}(U(C))$ where $C$ is a circuit of $K$ whose edges all occur in $W$. For atoms $a, b$ of $\Gamma$, let $a^{\prime}, b^{\prime}$ be the corresponding atoms of $K$ in the natural sense; we say $d(a, b)=0$ if $a=b, d(a, b)=\operatorname{ord}(\mathcal{T})$ if $a \neq b$ and there is no closed walk $W$ of length $<2 \operatorname{ord}(\mathcal{T})$ with $a^{\prime}, b^{\prime} \in \operatorname{ins}(W)$, and otherwise $d(a, b)$ is half the minimum length of such a walk. (See [7] for further discussion.) If $\{v\}$ is an atom of $\Gamma$ we often write $d(v, a)$ for $d(\{v\}, a)$. We call $d$ the metric of $\mathcal{T}$.

We need the following lemma.
5.1 For every surface $\Sigma$ and integer $p \geq 0$, there exists $\theta>p$ with the following property. Let $\Gamma$ be a drawing in $\Sigma$ with $|V(\Gamma) \cap b d(\Sigma)|=p$, and let $\mathcal{T}$ be a respectful tangle in $\Gamma$ of order $\geq \theta$. Suppose that
(i) there is no $\Gamma$-normal $O$-arc $F \subseteq \Sigma$ such that $|F \cap V(\Gamma)|<|C \cap V(\Gamma)|$ and $C \subseteq$ ins(F) for some cuff $C$ of $\Sigma$, and
(ii) for every two cuffs $C_{1}, C_{2}$, the corresponding cuff regions $r_{1}, r_{2}$ satisfy $d\left(r_{1}, r_{2}\right) \geq \theta$ where $d$ is the metric of $\mathcal{T}$.

Then there is no vital linkage in $\Gamma$ with set of terminals $V(\Gamma) \cap b d(\Sigma)$.
Proof. Choose $\theta^{\prime}$ so that theorem (3.2) of [7] holds, with $\Sigma, t, z$, and $\theta$ replaced by $\hat{\Sigma}, c(\Sigma), p$ and $\theta^{\prime}$ respectively. We may assume that $\theta^{\prime} \geq p+9$, by increasing $\theta^{\prime}$ if necessary. Let $\theta=2 \theta^{\prime}+1$. We claim that $\theta$ satisfies (5.1). For let $\Gamma, \mathcal{T}$ be as in (5.1), satisfying (i) and (ii). Let $d$ be the metric of $\mathcal{T}$. Now $\Gamma$ is 2-cell in $\hat{\Sigma}$ since $\mathcal{T}$ is respectful.
(1) There is a vertex $v$ of $\Gamma$ such that $d(v, r) \geq \theta^{\prime}$ for every cuff region $r$.

Subproof. We may assume that there is at least one cuff region $r_{1}$ say. By [4, theorem (8.9)], there is an edge $e$ of $\Gamma$ so that $d\left(e, r_{1}\right)=\operatorname{ord}(\mathcal{T})$. Let $v_{1}, \ldots, v_{n}$ be a sequence of vertices of $\Gamma$ such that $v_{1}$ is incident with $r_{1}, v_{n}$ is incident with $e$, and for $1 \leq i<n$ some region of $\Gamma$ in $\hat{\Sigma}$ is incident with $v_{i}$ and $v_{i}+1$. Then $d\left(r_{1}, v_{1}\right) \leq 1, d\left(e, v_{n}\right) \leq 2$, and $d\left(v_{i}, v_{i}+1\right) \leq 2$ for $1 \leq i<n$. Since $d\left(r_{1}, e\right)=\operatorname{ord}(\mathcal{T})$, it follows (since $d$ is a metric) that $d\left(r_{1}, v_{n}\right) \geq \operatorname{ord}(\mathcal{T})-2 \geq \theta^{\prime}$. Consequently we may choose $i$ with $1 \leq i \leq n$ minimum such that $d\left(r_{1}, v_{i}\right) \geq \theta^{\prime}$. Since $d\left(r_{1}, v_{1}\right) \leq 1$ and $\theta^{\prime} \geq 2$ it follows that $i \geq 2$. From the minimality of $i, d\left(r_{1}, v_{i-1}\right)<\theta^{\prime}$. Since $d\left(v_{i-1}, v_{i}\right) \leq 2$ it follows that $d\left(r_{1}, v_{i}\right) \leq \theta^{\prime}+1$. For any cuff region $r_{2} \neq r_{1}$,

$$
\theta \leq d\left(r_{1}, r_{2}\right) \leq d\left(r_{1}, v_{i}\right)+d\left(r_{2}, v_{i}\right) \leq \theta^{\prime}+1+d\left(r_{2}, v_{i}\right)
$$

by (ii), and so $d\left(r_{2}, v_{i}\right) \geq \theta-\theta^{\prime}-1=\theta^{\prime}$. Thus setting $v=v_{i}$ satisfies (1). This proves (1).

Let $v$ be as in (1).
(2) If $\Gamma \backslash v$ is not 2 -cell in $\hat{\Sigma}$ then there is no vital linkage in $\Gamma$ with set of terminals $V(\Gamma) \cap b d(\Sigma)$.

Subproof. Suppose that $L$ is a vital linkage in $\Gamma$ with set of terminals $V(\Gamma) \cap b d(\Sigma)$, and that $r$ is a region of $\Gamma \backslash v$ in $\hat{\Sigma}$ which is not homeomorphic to an open disc. Consequently $v \in r$. Since $r$ is not homeomorphic to an open disc there is by [5, theorem (4.2)] an $O$-arc $F \subseteq r$ which bounds no disc in $r$; and it can be chosen so that $F \cap U(\Gamma)=\{v\}$. Since $|F \cap V(\Gamma)| \leq 1$ it follows that $\operatorname{ins}(F)$ exists, and $\operatorname{ins}(F) \nsubseteq r$. Consequently, $\operatorname{ins}(F) \cap U(\Gamma \backslash v) \neq \emptyset$. Since $L$ is vital there exists a component of $P$ of $L$ with $V(P) \cap \operatorname{ins}(F) \nsubseteq F$, and it follows that one end $s$ of $P$ is in $\operatorname{ins}(F) \backslash F$, since $V(P) \cap F \subseteq\{v\}$. Let $r_{1}$ be the cuff region with $s \in \bar{r}_{1}$. Then $\bar{r}_{1} \cap(\operatorname{ins}(F) \backslash F) \neq \emptyset$, and so $d\left(r_{1}, v\right) \leq 1$, contrary to (1). This proves (2).

Let $\Gamma^{\prime}=\Gamma \backslash v$. By (2), we may assume that $\Gamma$ is 2-cell in $\hat{\Sigma}$. Since $d(\{v\}, e) \leq 2$ for every edge $e$ of $\Gamma$ not in $\Gamma^{\prime}$, and $\operatorname{ord}(\mathcal{T}) \geq \theta^{\prime} \geq 7$, it follows from theorem (7.8) of [7] that
(3) There is a respectful tangle $\mathcal{T}^{\prime}$ in $\Gamma^{\prime}$ of $\operatorname{order} \operatorname{ord}(\mathcal{T})-4$, such that
(i) $\left(A \cap \Gamma^{\prime}, B \cap \Gamma^{\prime}\right) \in \mathcal{T}^{\prime}$ for every $(A, B) \in \mathcal{T}$ of $\operatorname{order}<\operatorname{ord}(\mathcal{T})-4$, and
(ii) if $a, b \in A(\Gamma, \hat{\Sigma})$ and $a^{\prime}, b^{\prime} \in A\left(\Gamma^{\prime}, \hat{\Sigma}\right)$ satisfy $a \subseteq a^{\prime}$ and $b \subseteq b^{\prime}$, then

$$
d(a, b) \geq d^{\prime}\left(a^{\prime}, b^{\prime}\right) \geq d(a, b)-8
$$

where $d^{\prime}$ is the metric of $\mathcal{T}^{\prime}$.

Let $i n s^{\prime}$ be the function derived from $\mathcal{T}^{\prime}$ analogous to ins.
(4) If $F \subseteq \Sigma$ is a $\Gamma^{\prime}$-normal $O$-arc with $\left|F \cap V\left(\Gamma^{\prime}\right)\right|<\left|C \cap V\left(\Gamma^{\prime}\right)\right|$ for some cuff $C$, then $C \nsubseteq$ ins $^{\prime}(F)$.

Subproof. Let $r_{1}$ be the cuff region of $\Gamma$ in $\hat{\Sigma}$ corresponding to $C$. Since $d\left(r_{1}, v\right) \geq 2$ it follows that $v$ is not incident with $r_{1}$ and so $r_{1}$ is also the cuff region of $\Gamma^{\prime}$ in $\hat{\Sigma}$ corresponding to $C$. Let $r$ be the region of $\Gamma^{\prime}$ with $v \in r$. If $F \cap r \neq \emptyset$, then

$$
d^{\prime}\left(r, r_{1}\right) \leq\left|F \cap V\left(\Gamma^{\prime}\right)\right|<\left|C \cap V\left(\Gamma^{\prime}\right)\right| \leq|b d(\Sigma) \cap V(\Gamma)|=p
$$

and so by (3)(ii), $d\left(v, r_{1}\right) \leq p+8$, contrary to (1) since $\theta^{\prime} \geq p+9$. Consequently $F \cap r=\emptyset$, and so $F$ is $\Gamma$-normal, and $|F \cap V(\Gamma)|<|C \cap V(\Gamma)|$. From (i) it follows that $C \nsubseteq \operatorname{ins}(F)$. Let $\Delta=\operatorname{ins}(F)$. Then
$(\Gamma \cap \Delta, \Gamma \cap \overline{\Sigma \backslash \Delta}) \in \mathcal{T}$, and has order $<k \leq \operatorname{ord}(\mathcal{T})-4$ and so by $(3)(\mathrm{i}),\left(\Gamma^{\prime} \cap \Delta, \Gamma^{\prime} \cap \overline{\Sigma \backslash \Delta}\right) \in \mathcal{T}^{\prime}$. Consequently, $\Delta=$ ins $^{\prime}(F)$. This proves (4).
(5) For every two distinct cuffs $C_{1}, C_{2}$, the corresponding cuff regions $r_{1}, r_{2}$ of $\Gamma^{\prime}$ in $\hat{\Sigma}$ are distinct and satisfy $d^{\prime}\left(r_{1}, r_{2}\right) \geq \theta^{\prime}$.

Subproof. As we saw in (4), $r_{1}$ and $r_{2}$ are cuff regions of $\Gamma$ in $\hat{\Sigma}$. Since $d\left(r_{1}, r_{2}\right) \geq \theta$ by hypothesis, it follows that $r_{1} \neq r_{2}$. By (3)(ii),

$$
d^{\prime}\left(r_{1}, r_{2}\right) \geq d\left(r_{1}, r_{2}\right)-8 \geq \theta-8 \geq \theta^{\prime} .
$$

This proves (5).

Suppose that $L$ is a linkage in $\Gamma$ with set of terminals $V(\Gamma) \cap b d(\Sigma)$. From (4), (5) and theorem (3.2) of [7], there is a linkage in $\Gamma \backslash v$ with the same pattern as $L$, from the choice of $\theta^{\prime}$. But then $L$ is not vital. The result follows.

The main result of this section is the following.
5.2 For every surface $\Sigma$ with $b d(\Sigma)=\emptyset$ and every integer $p \geq 0$ there exists $\theta \geq 1$ such that every drawing in $\Sigma$ with a tangle of order $\geq \theta$ has no vital p-linkage.

Proof. Let $\Sigma_{0}$ be a surface with $b d\left(\Sigma_{0}\right)=\emptyset$, and assume that the result holds for all pairs $\Sigma^{\prime}, p^{\prime}$ where $\Sigma^{\prime}$ is simpler than $\Sigma_{0}$. We shall prove that it holds for $\Sigma_{0}$ and all $p$. By cutting at most $p$ small holes in $\Sigma_{0}$, one at each terminal, we deduce that it suffices to prove the following.
(*) For every surface $\Sigma$ with $\hat{\Sigma}$ homeomorphic to $\Sigma_{0}$ and every integer $p \geq 0$, there exists $\theta \geq 1$ such that every drawing $\Gamma$ in $\Sigma$ with $|V(\Gamma) \cap b d(\Sigma)| \leq p$ and with a tangle of order $\geq \theta$ has no vital linkage with all its terminals in $b d(\Sigma)$.

We shall prove $(*)$ for all $p$ by induction on $c(\Sigma)$, and then, with $c(\Sigma)$ fixed, by induction on $p$. Our three inductive hypothesis may be summarized as follows.
(1) For all $p^{\prime} \geq 0$ there exists $\theta_{1}\left(p^{\prime}\right) \geq 1$ such that for every surface $\Sigma^{\prime}$ with $b d\left(\Sigma^{\prime}\right)=\emptyset$ which is simpler than $\Sigma_{0}$, every drawing in $\Sigma^{\prime}$ with a tangle of order $\geq \theta_{1}\left(p^{\prime}\right)$ has no vital $p^{\prime}$-linkage.
(2) For all $p^{\prime} \geq 0$ there exists $\theta_{2}\left(p^{\prime}\right) \geq 1$ such that for every surface $\Sigma^{\prime}$ with $\hat{\Sigma}^{\prime}$ homeomorphic to $\Sigma_{0}$ and $c\left(\Sigma^{\prime}\right)<c(\Sigma)$, every drawing $\Gamma^{\prime}$ in $\Sigma^{\prime}$ with $\left|V\left(\Gamma^{\prime}\right) \cap b d\left(\Sigma^{\prime}\right)\right| \leq p^{\prime}$ with a tangle of order $\geq \theta_{2}\left(p^{\prime}\right)$ has no vital linkage with all its terminals in $b d\left(\Sigma^{\prime}\right)$.
(3) There exists $\theta_{3} \geq 1$ such that for every surface $\Sigma^{\prime}$ homeomorphic to $\Sigma$, every drawing $\Gamma^{\prime}$ in $\Sigma^{\prime}$ with $\left|V\left(\Gamma^{\prime}\right) \cap b d\left(\Sigma^{\prime}\right)\right|<p$ with a tangle of order $\geq \theta_{3}$ has no vital linkage with all its terminals in $b d\left(\Sigma^{\prime}\right)$.

Choose $\theta_{4}>p$ such that (5.1) holds (with $\theta$ replaced by $\theta_{4}$ ). Let

$$
\theta=2 \theta_{4}+\max \left(\theta_{1}\left(p+3 \theta_{4}\right), \theta_{2}\left(p+3 \theta_{4}\right), \theta_{3}\right) .
$$

We claim that $\theta$ satisfies (*). For suppose not, and let $\Gamma$ be a drawing in $\Sigma$ with $|V(\Gamma) \cap b d(\Sigma)| \leq p$, let $\mathcal{T}$ be a tangle in $\Gamma$ of order $\geq \theta$, and let $L$ be a vital linkage in $\Gamma$ with all its terminals in $b d(\Sigma)$. Choose $\Gamma, \mathcal{T}, L$ so that $\Gamma$ is minimal.
(4) $\Gamma$ is connected and loopless.

Subproof. If $\Gamma$ is not connected, there exists $\left(\Gamma_{1}, \Gamma_{2}\right) \in \mathcal{T}$ of order 0 with $\Gamma_{2} \neq \Gamma$. By (3.3), $\Gamma_{2}$ has a tangle of order $\geq \theta$, and $\left|V\left(\Gamma_{2}\right) \cap b d(\Sigma)\right| \leq p$, and $L \cap \Gamma_{2}$ is a vital linkage in $\Gamma_{2}$ with all its terminals in $b d(\Sigma)$. This contradicts the minimality of $\Gamma$. Thus, $\Gamma$ is connected, and by theorem (8.4) of [6] and the minimality of $\Gamma$ it is also loopless. This proves (4).
(5) Suppose that $(A, B) \in \mathcal{T}$ has order $\leq \theta_{4}$, and $\Gamma^{\prime}$ is a drawing in a surface $\Sigma^{\prime}$, such that $\Gamma^{\prime}$ can be obtained from $B$ by splitting $\leq \theta_{4}$ vertices of $B$. Then $\hat{\Sigma}^{\prime}$ is not simpler than $\Sigma_{0}$.

Subproof. From (3.3), $B$ has a tangle of order $\geq \theta-\theta_{4}$, and so $\Gamma^{\prime}$ has a tangle of order $\geq \theta-2 \theta_{4}$. But from (2.2) and (2.3), $B$ has a vital $\left(p+\theta_{4}\right)$-linkage, and so from (2.4), $\Gamma^{\prime}$ has a vital $\left(p+3 \theta_{4}\right)$ linkage. Since $\theta-2 \theta_{4} \geq \theta_{1}\left(p+3 \theta_{4}\right)$, it follows from (1) that $\hat{\Sigma}^{\prime}$ is not simpler than $\Sigma_{0}$. This proves (5).
(6) Suppose that $(A, B) \in \mathcal{T}$ has order $\leq \theta_{4}$, and $\Gamma^{\prime}$ is a drawing in a surface $\Sigma^{\prime}$, such that $\Gamma^{\prime}$ can be obtained from $B$ by splitting $\leq \theta_{4}$ vertices of $B$. Suppose, moreover, that
(a) $\hat{\Sigma}^{\prime}$ is homeomorphic to $\Sigma_{0}$, and
(b) for $v \in V\left(\Gamma^{\prime}\right), v \in b d\left(\Sigma^{\prime}\right)$ if and only if either $v \in V(A \cap B)$, or $v \in V(\Gamma) \cap b d(\Sigma)$, or $v \notin V(\Gamma)$ (that is, $v$ is a new vertex produced by splitting).

Then $c\left(\Sigma^{\prime}\right) \geq c(\Sigma)$, and if equality holds then $\left|V\left(\Gamma^{\prime}\right) \cap b d\left(\Sigma^{\prime}\right)\right| \geq p$.

Subproof. As in (5), $\Gamma^{\prime}$ has a tangle of order $\geq \theta-2 \theta_{4}$, and has a vital linkage with all its terminals in $b d\left(\Sigma^{\prime}\right)$ (from (b)). But

$$
\left|V\left(\Gamma^{\prime}\right) \cap b d\left(\Sigma^{\prime}\right)\right| \leq|V(A \cap B)|+|V(\Gamma) \cap b d(\Sigma)|+2 \theta_{4} \leq p+3 \theta_{4}
$$

and $\theta-2 \theta_{4} \geq \theta_{2}\left(p+3 \theta_{4}\right)$, and so from (2) and (a), $c\left(\Sigma^{\prime}\right) \geq c(\Sigma)$. If equality holds then $\Sigma^{\prime}$ is homeomorphic to $\Sigma$, and since $\theta-2 \theta_{4} \geq \theta_{3}$ it follows that $\left|V\left(\Gamma^{\prime}\right) \cap b d\left(\Sigma^{\prime}\right)\right| \geq p$, from (3). This proves (6).
(7) There is no $\Gamma$-normal proper line $F \subseteq \Sigma$ with ends in different cuffs such that $|F \cap V(\Gamma)| \leq \theta_{4}$.

Subproof. If there is such an $F$, let $A$ be null and $B=\Gamma$; let $\Sigma^{\prime}$ be obtained from $\Sigma$ by cutting along $F$, and let $\Gamma^{\prime}$ be obtained from $\Gamma$ by splitting appropriately the vertices of $\Gamma$ in $F$. (Since $\Gamma$ is loopless we can do so.) By (4.1)(i), $\hat{\Sigma}^{\prime}$ is homeomorphic to $\Sigma_{0}$ and $c\left(\Sigma^{\prime}\right)=c(\Sigma)-1$, contrary to (6). This proves (7).

Let $\mathcal{T}_{1}$ be the $\theta_{4}$-truncation of $\mathcal{T}$.
(8) $\mathcal{T}_{1}$ is respectful.

Subproof. Certainly $\Gamma$ is connected, by (4). Let $F \subseteq \hat{\Sigma}$ be a $\Gamma$-normal $O$-arc with $|F \cap V(\Gamma)|<\theta_{4}$. Suppose first that $F$ does not separate $\hat{\Sigma}$, let $\Sigma^{\prime}$ be obtained from $\hat{\Sigma}$ by cutting along $F$, and let $\Gamma^{\prime}$ be the drawing in $\Sigma^{\prime}$ obtained from $\Gamma$ by splitting appropriately the vertices of $\Gamma$ in $F$. By (4.1)(iii) $\hat{\Sigma}^{\prime}$ is simpler than $\Sigma_{0}$, contrary to (5). Thus $F$ separates $\hat{\Sigma}$. Let $\Sigma_{1}, \Sigma_{2} \subseteq \hat{\Sigma}$ be surfaces such that $\Sigma_{1} \cup \Sigma_{2}=\hat{\Sigma}$ and $\Sigma_{1} \cap \Sigma_{2}=F$. Let $\Gamma_{i}=\Gamma \cap \Sigma_{i}(i=1,2)$. Since $\left(\Gamma_{1}, \Gamma_{2}\right)$ is a separation of $\Gamma$ of order $<\theta_{4}$, we may assume that $\left(\Gamma_{1}, \Gamma_{2}\right) \in \mathcal{T}_{1} \subseteq \mathcal{T}$. By (5), $\hat{\Sigma}_{2}$ is not simpler than $\Sigma_{0}$, and so by (4.2)(iii), $\Sigma_{1}$ is a disc. This proves (8).

If $F \subseteq \hat{\Sigma}$ is a $\Gamma$-normal $O$-arc with $|F \cap V(\Gamma)|<\theta_{4}$, we define $\operatorname{ins}(F)$ as usual.
(9) If $F \subseteq \hat{\Sigma}$ is a $\Gamma$-normal $O$-arc with $|F \cap V(\Gamma)|<\theta_{4}$, then $C \cap \operatorname{ins}(F) \neq \emptyset$ for at most one cuff $C$.

Subproof. Let $A=\Gamma \cap \operatorname{ins}(F)$ and choose $B \subseteq \Gamma$ so that $(A, B)$ is a separation of $\Gamma$ and $V(A \cap B)=V(\Gamma) \cap F$. If $C \cap \operatorname{ins}(F) \neq \emptyset$ for $\geq 2$ cuffs $C$, then by splitting $\leq 2$ vertices of $B$, we can obtain from $B$ a drawing $\Gamma^{\prime}$ in a surface $\Sigma^{\prime}$ with $\hat{\Sigma}^{\prime}$ homeomorphic to $\Sigma_{0}$ and with $c\left(\Sigma^{\prime}\right)<c(\Sigma)$, satisfying (6)(b), contrary to (6). This proves (9).

Let $d_{1}$ be the metric of $\mathcal{T}_{1}$.
(10) If $r_{1}, r_{2}$ are the cuff regions corresponding to distinct cuffs $C_{1}, C_{2}$ then $d_{1}\left(r_{1}, r_{2}\right) \geq \theta_{4}$.

Subproof. Suppose not. From (7), (9) and the definition of the metric, and exchanging $C_{1}$ and $C_{2}$ if necessary, there is a $\Gamma$-normal $O$-arc $F_{1} \subseteq \Sigma \backslash b d(\Sigma)$ with $\left|F_{1} \cap V(\Gamma)\right|<\theta_{4}$, and with $r_{1} \subseteq \operatorname{ins}\left(F_{1}\right) \backslash F_{1}$, such that $\operatorname{ins}\left(F_{1}\right) \cap b d(\Sigma)=C_{1}$. Moreover, there is also either
(i) a $\Gamma$-normal line $F_{0} \subseteq \Sigma$ with one end in $F_{1}$, the other end in $C_{2}$, and with no internal point in $b d(\Sigma) \cup \operatorname{ins}\left(F_{1}\right)$, with $\left|\left(F_{0} \cup F_{1}\right) \cap V(\Gamma)\right|<\theta_{4}$, or
(ii) a $\Gamma$-normal $O$-arc $F_{2} \subseteq \Sigma \backslash b d(\Sigma)$ with $\left|\left(F_{1} \cup F_{2}\right) \cap V(\Gamma)\right|<\theta_{4}$ and with $r_{2} \subseteq \operatorname{ins}\left(F_{2}\right) \backslash F_{2}$, such that $\operatorname{ins}\left(F_{2}\right) \cap b d(\Sigma)=C_{2}$ and $\left|\operatorname{ins}\left(F_{1}\right) \cap \operatorname{ins}\left(F_{2}\right)\right|=1$, or
(iii) a $\Gamma$-normal $O$-arc $F_{2} \subseteq \Sigma \backslash b d(\Sigma)$ and a $\Gamma$-normal line $F_{0} \subseteq \Sigma \backslash b d(\Sigma)$ with $\left|\left(F_{0} \cup F_{1} \cup F_{2}\right) \cap V(\Gamma)\right|<$ $\theta_{4}$, such that $r_{2} \subseteq \operatorname{ins}\left(F_{2}\right) \backslash F_{2}, \operatorname{ins}\left(F_{2}\right) \cap b d(\Sigma)=C_{2}, \operatorname{ins}\left(F_{1}\right) \cap \operatorname{ins}\left(F_{2}\right)=\emptyset$, one end of $F_{0}$ is in $F_{1}$, the other end is in $F_{2}$, and no internal point of $F_{0}$ is in $\operatorname{ins}\left(F_{1}\right)$ or $\operatorname{ins}\left(F_{2}\right)$.

If (i) holds, let $A=\Gamma \cap \operatorname{ins}\left(F_{1}\right)$, and let $(A, B) \in \mathcal{T}$ where $V(A \cap B)=F \cap V(\Gamma)$; then (6) is contradicted, by splitting all the vertices of $B$ in $F_{0}$. If (ii) or (iii) holds, let

$$
A=\left(\Gamma \cap i n s\left(F_{1}\right)\right) \cup\left(\Gamma \cap i n s\left(F_{2}\right)\right)
$$

and let $(A, B) \in \mathcal{T}$ where $V(A \cap B)=\left(F_{1} \cup F_{2}\right) \cap V(\Gamma)$; then again (6) is contradicted, in (ii) by splitting the vertex of $B$ in $F_{1} \cap F_{2}$ if there is one, and in (iii) by splitting all the vertices of $B$ in $F_{0}$. This proves (10).
(11) If $F \subseteq \Sigma$ is a $\Gamma$-normal $O$-arc with $|F \cap V(\Gamma)|<\theta_{4}$, and ins $(F)$ includes a unique cuff $C$, then $|F \cap V(\Gamma)| \geq|C \cap V(\Gamma)|$.

Subproof. By (9), ins $(F) \cap b d(\Sigma)=C$. Let $A=\Gamma \cap \operatorname{ins}(F)$, and let $(A, B) \in \mathcal{T}$ where $V(A \cap B)=$ $F \cap V(\Gamma)$. Let $\Sigma^{\prime}$ be obtained from $\Sigma$ by deleting $\Sigma \cap(\operatorname{ins}(F) \backslash F)$. Then $\Sigma^{\prime}$ is homeomorphic to $\Sigma$, and so by (6),

$$
\left|V(B) \cap b d\left(\Sigma^{\prime}\right)\right| \geq p \geq|V(\Gamma) \cap b d(\Sigma)| .
$$

Consequently $|F \cap V(\Gamma)| \geq|C \cap V(\Gamma)|$. This proves (11).
(12) Every vertex in $V(\Gamma) \cap b d(\Sigma)$ is a terminal of $L$.

Subproof. If $v \in b d(\Sigma) \backslash V(\Gamma)$ is not a terminal of $L$, let $\Sigma^{\prime}$ be obtained from $\Sigma$ by slightly enlarging $\Sigma$ in the neighbourhood of $v$. Then $\left|V(\Gamma) \cap b d\left(\Sigma^{\prime}\right)\right|<p$, contrary to (3). This proves (12).

But (8), (10), (11) and (12) contradict (5.1). Thus our assumption that $\theta$ does not satisfy (*) was false, and the proof is complete.

## 6 Presentations

If $\Gamma$ is a drawing in a surface $\Sigma$ such that $|V(\Gamma) \cap C| \geq 2$ for every cuff $C$, we call the connected components of $b d(\Sigma) \backslash V(\Gamma)$ the spaces of $\Gamma$ in $\Sigma$. For every space $s$ there are two vertices $u, v$ such that $s \cup\{u, v\}$ is a line; we call $u, v$ the ends of $s$. A support of $\Gamma$ in $\Sigma$ is either a set $\{v\}$ where $v \in V(\Gamma) \cap b d(\Sigma)$, or a line $F \subseteq b d(\Sigma)$ with both ends in $V(\Gamma)$ (where possibly some internal points of $F$ belong to $V(\Gamma))$. The ends of a support $F$ are $a$ and $b$, where $a=b=v$ if $F=\{v\}$, and $a$ and $b$ are the ends of the line $F$ if $F$ is a line.

Let $\Gamma$, as above, be a subgraph of some graph $G$, which is not required to be a drawing. Let $F_{1}^{*}, \ldots, F_{r}^{*}$ be mutually disjoint supports of $\Gamma$ in $\Sigma$ with $V(\Gamma) \cap b d(\Sigma) \subseteq F_{1}^{*} \cup \cdots \cup F_{r}^{*}$. For $1 \leq j \leq r$, let $H_{j} \subseteq G$, so that
(V1) $H_{1} \cup \ldots \cup H_{r} \cup \Gamma=G ; H_{1}, \ldots, H_{r}$ are mutually vertex-disjoint; and for $1 \leq j \leq r, V\left(H_{j} \cap \Gamma\right)=$ $V(\Gamma) \cap F_{j}^{*}$, and $E\left(H_{j} \cap \Gamma\right)=\emptyset$.

For $1 \leq j \leq r$, let $q_{j} \geq 1$ be an integer; for each $u \in V(\Gamma) \cap F_{j}^{*}$ let $\mu(u)$ be an edge-less subgraph of $H_{j}$ with $q_{j}$ vertices and with $V(\mu(u) \cap \Gamma)=\{u\}$; and for each space $s$ with $s \subseteq F_{j}^{*}$, let $\mu(s)$ be a subgraph of $H_{j}$, satisfying the following. (For a support $F$ of $\Gamma$ in $\Sigma, \mu(F)$ denotes the union of $\mu(s)$ over all spaces $s \subseteq F$ and $\mu(u)$ over all $u \in F \cap V(\Gamma)$.)
(V2) For $1 \leq j \leq r, H_{j}=\mu\left(F_{j}^{*}\right)$.
(V3) For $1 \leq j \leq r$, if $s \subseteq F_{j}^{*}$ is a space with ends $u_{1}, u_{2}$, then $V(\mu(s) \cap \Gamma)=\left\{u_{1}, u_{2}\right\}$, and $\mu\left(u_{1}\right), \mu\left(u_{2}\right) \subseteq \mu(s)$ and there are $q_{j}$ mutually vertex-disjoint paths of $\mu(s)$ between $V\left(\mu\left(u_{1}\right)\right)$ and $V\left(\mu\left(u_{2}\right)\right)$.
(V4) For $1 \leq j \leq r$, if $s_{1}, s_{2} \subseteq F_{j}^{*}$ are spaces, and $u \in F_{j}^{*} \cap V(\Gamma)$ lies between them in $F_{j}^{*}$, then $\mu\left(s_{1}\right) \cap \mu\left(s_{2}\right) \subseteq \mu(u)$ (and consequently $E\left(\mu\left(s_{1}\right) \cap \mu\left(s_{2}\right)\right)=\emptyset$ ).

In these circumstances, we call $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, H_{1}, \ldots, H_{r}, \mu$ a presentation of $G$ in $\Sigma$, with defect $r$. Its depth is $\max \left(q_{j}: 1 \leq j \leq r\right)$, or 0 if $r=0$ (which implies $b d(\Sigma)=\emptyset$ ). Our next goal is to prove a form of (1.1) for graphs with presentations with given defect and depth, in a fixed surface. We use the following lemma.
6.1 Let $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, H_{1}, \ldots, H_{r}, \mu$ be a presentation of $G$ in $\Sigma$. Let $a, b, a^{\prime}, b^{\prime} \in F_{1}^{*} \cap V(\Gamma)$ be in order and let $I, I^{\prime} \subseteq F_{1}^{*}$ be the supports with ends $a, b$ and $a^{\prime}, b^{\prime}$ respectively. Let $|\mu(a)|=q$; let $P_{1}, \ldots, P_{q}$ be mutually vertex-disjoint paths of $\mu(I)$ between $V(\mu(a))$ and $V(\mu(b))$; and let $P_{1}^{\prime}, \ldots, P_{q}^{\prime}$ be mutually vertex-disjoint paths of $\mu\left(I^{\prime}\right)$ between $V\left(\mu\left(a^{\prime}\right)\right)$ and $V\left(\mu\left(b^{\prime}\right)\right)$.
(i) For $1 \leq i, i^{\prime} \leq q$, if $v \in V\left(P_{i} \cap P_{i^{\prime}}^{\prime}\right)$, then $v \in V\left(\mu(b) \cap \mu\left(a^{\prime}\right)\right)$ and $v$ is an end of $P_{i}$ and of $P_{i^{\prime}}^{\prime}$.
(ii) If $a^{\prime}=b$, then $P_{1}, \ldots, P_{q}$ can be renumbered so that $P_{1} \cup P_{1}^{\prime}, \ldots, P_{q} \cup P_{q}^{\prime}$ are mutually vertexdisjoint paths of $\mu\left(I \cup I^{\prime}\right)$ between $V(\mu(a))$ and $V\left(\mu\left(b^{\prime}\right)\right)$.
(iii) If $\left|\mu(a) \cup \mu\left(b^{\prime}\right)\right|=\left|\mu\left(a^{\prime}\right) \cup \mu(b)\right|=k$ say, then $\left\{P_{1}, \ldots, P_{q}, P_{1}^{\prime}, \ldots, P_{q}^{\prime}\right\}$ has cardinality $k$, and its members are $k$ mutually vertex-disjoint paths of $\mu(I) \cup \mu\left(I^{\prime}\right)$ between $V\left(\mu(a) \cup \mu\left(b^{\prime}\right)\right)$ and $V\left(\mu(b) \cup \mu\left(a^{\prime}\right)\right)$.

Proof. First we prove (i). Let $v \in V\left(P_{i} \cap P_{i^{\prime}}^{\prime}\right)$, where $1 \leq i, i^{\prime} \leq q$. We claim that $v \in V(\mu(b))$. If $a=b$ this is clear since

$$
v \in V\left(P_{i}\right) \subseteq V(\mu(I))=V(\mu(b))
$$

and so we assume that $a \neq b$. Consequently there is a space $s \subseteq I$ with $v \in V(\mu(s))$. Let $J \subseteq F_{1}^{*}$ be the support with ends $b$ and $b^{\prime}$. Since $I^{\prime} \subseteq J$ it follows that $v \in V(\mu(J))$. If $b=b^{\prime}$ then $v \in V(\mu(b))$ by the same argument as above applied to $J$ instead of $I$, and so we may assume that $b \neq b^{\prime}$. Hence there is a space $s^{\prime} \subseteq J$ with $v \in V\left(\mu\left(s^{\prime}\right)\right)$. Now $b$ lies in $F_{1}^{*}$ between $s$ and $s^{\prime}$, and so $v \in V(\mu(b))$ by (V4). This proves our claim that $v \in V(\mu(b))$.

Now since $|V(\mu(b))|=q$ and each of $P_{1}, \ldots, P_{q}$ has an end in $V(\mu(b))$, it follows that each vertex of $\mu(b)$ is an end of one of $P_{1}, \ldots, P_{q}$, and in particular, $v$ is an end of one of $P_{1}, \ldots, P_{q}$. Since $v \in V\left(P_{i}\right)$ and $P_{1}, \ldots, P_{q}$ are mutually vertex-disjoint, it follows that $v$ is an end of $P_{i}$. Similarly, $v \in V\left(\mu\left(a^{\prime}\right)\right)$ and $v$ is an end of $P_{i^{\prime}}^{\prime}$. This proves (i).

For (ii), let $P_{1}, \ldots, P_{q}$ and $P_{1}^{\prime}, \ldots, P_{q}^{\prime}$ be numbered so that for $1 \leq i \leq q, P_{i}$ and $P_{i}^{\prime}$ have a common end in $V(\mu(b))$. For $1 \leq i, i^{\prime} \leq q$, if $i \neq i^{\prime}$ it follows from (i) that $P_{i}$ is vertex-disjoint from $P_{i^{\prime}}^{\prime}$; and so $P_{1} \cup P_{1}^{\prime}, \ldots, P_{q} \cup P_{q}^{\prime}$ are mutually vertex-disjoint paths satisfying (ii).

For (iii), let $\mu(a)=\left\{a_{1}, \ldots, a_{q}\right\}, \mu(b)=\left\{b_{1}, \ldots, b_{q}\right\}, \mu\left(a^{\prime}\right)=\left\{a_{1}^{\prime}, \ldots, a_{q}^{\prime}\right\}, \mu\left(b^{\prime}\right)=\left\{b_{1}^{\prime}, \ldots, b_{q}^{\prime}\right\}$, numbered so that for $1 \leq i \leq q, P_{i}$ has ends $a_{i}$ and $b_{i}$, and $P_{i}^{\prime}$ has ends $a_{i}^{\prime}$ and $b_{i}^{\prime}$, and for $1 \leq i, i^{\prime} \leq q$, if $i \neq i^{\prime}$ then $b_{i} \neq a_{i^{\prime}}^{\prime}$. Suppose that $1 \leq i, i^{\prime} \leq q$ and $a_{i}=b_{i^{\prime}}^{\prime}$. By (i), $i=i^{\prime}$ and $a_{i}=b_{i}=a_{i}^{\prime}=b_{i}^{\prime}$, and so $P_{i}=P_{i^{\prime}}^{\prime}$. In particular, for $1 \leq i, i^{\prime} \leq q$, if $i \neq i^{\prime}$ then $P_{i}$ and $P_{i^{\prime}}^{\prime}$ are vertex-disjoint. Thus

$$
\begin{aligned}
\left\{i: 1 \leq i \leq q, a_{i}=b_{i^{\prime}}^{\prime}\right\} & \subseteq\left\{i: 1 \leq i \leq q, P_{i}=P_{i}^{\prime}\right\} \\
& \subseteq\left\{i: 1 \leq i \leq q, V\left(P_{i} \cap P_{i}^{\prime}\right) \neq \emptyset\right\}=\left\{i: 1 \leq i \leq q, a_{i}^{\prime}=b_{i}\right\}
\end{aligned}
$$

But from the hypothesis of (iii), $\left|\mu(a) \cup \mu\left(b^{\prime}\right)\right|=\left|\mu\left(a^{\prime}\right) \cup \mu(b)\right|$, and so

$$
\left|\left\{i: 1 \leq i \leq q, a_{i}=b_{i}^{\prime}\right\}\right|=\left|\left\{i: 1 \leq i \leq q, a_{i}^{\prime}=b_{i}\right\}\right| .
$$

We therefore have equality throughout, and in particular for $1 \leq i \leq q$, if $P_{i}$ meets $P_{i}^{\prime}$ then $P_{i}=P_{i}^{\prime}$. Then (iii) follows.
6.2 Let $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, H_{1}, \ldots, H_{r}, \mu$ be a presentation of a graph $G$ in some surface $\Sigma$. Let $I \subseteq F_{1}^{*}$ be a support with ends $a, b$. Then there are $|V(\mu(a))|$ mutually vertex-disjoint paths of $\mu(I)$ between $V(\mu(a))$ and $V(\mu(b))$.

Proof. This follows by induction on the number of spaces included in $I$, applying (6.1)(ii) if $I$ has an internal point in $V(\Gamma)$, and applying (V3) otherwise.

Let $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, H_{1}, \ldots, H_{r}, \mu$ be a presentation of $G$ in $\Sigma$, and let $L$ be a vital linkage in $G$. If $\Gamma \subseteq L$ and every terminal of $L$ is in one of $H_{1}, \ldots, H_{r}$, we say that $L$ is exhaustive (for the presentation). If $L$ is exhaustive then it follows that $\Gamma$ is a forest and every vertex of $\Gamma$ not in $b d(\Sigma)$ has degree 2 in $\Gamma$. Let us say a $\Sigma$-jump is a path in $\Gamma$ with distinct ends both in $b d(\Sigma)$ and with no internal vertex in $b d(\Sigma)$. If $L$ is exhaustive, then every edge of $\Gamma$ is in a unique $\Sigma$-jump, and any two $\Sigma$-jumps have no common vertices except possibly one end. The main result of this section is the following.
6.3 For every surface $\Sigma$ and all integers $p, r \geq 0$ and $q \geq 1$, there exists $\lambda \geq 0$ such that, if $G$ is a graph with a presentation in $\Sigma$ of depth $\leq q$ and defect $\leq r$, and there is an exhaustive vital p-linkage in $G$, then there are at most $\lambda \Sigma$-jumps.

The most difficult step in the proof of (6.3) is where $\Sigma$ is a disc and $r=1$. Then the cases when $\Sigma$ is a disc and $r=2,3$ and at least 4 are successively easier, and finally the case when $\Sigma$ is not a disc is also quite easy.
6.4 For all integers $p \geq 0$ and $q \geq 1$ there exists $\lambda \geq 0$ such that, if $G$ has a presentation in a disc $\Sigma$ of depth $\leq q$ and defect 1 , and there is an exhaustive vital p-linkage in $G$, then there are at most $\lambda \Sigma$-jumps.

Proof. Choose $n$ so that (2.6) holds, with $k$ replaced by $2 q$. Let $\lambda=n^{n}$. We claim that (6.2) is satisfied. For let $\Gamma, F^{*}, H, \mu$ be a presentation of $G$ in a disc $\Sigma$ with depth $\leq q$ and let $L$ be a vital $p$-linkage which is exhaustive for the presentation.

A line $F \subseteq \Sigma$ is good if it is proper, both its ends are in $V(\Gamma)$, and no internal point is in $U(\Gamma)$. If $F$ is a good line, there are two lines $J(F), K(F) \subseteq b d(\Sigma)$ with the same ends as $F$, where $K(F) \subseteq F^{*}$. Let $\Delta(F)$ be the closed disc in $\Sigma$ bounded by $F \cup K(F)$. Define

$$
\begin{aligned}
& A(F)=(\Gamma \cap \overline{\Sigma \backslash \Delta(F)}) \cup \mu(J(F)) \\
& B(F)=(\Gamma \cap \Delta(F)) \cup \mu(K(F)) \\
& X(F)=V(A(F) \cap B(F)) .
\end{aligned}
$$

(1) $(A(F), B(F))$ is a separation of $G$, and $X(F)=V\left(\mu\left(u_{1}\right) \cup \mu\left(u_{2}\right)\right)$ where $F$ has ends $u_{1}, u_{2}$.

The proof is similar to that of theorem (2.1) of [10] and we omit it.

Let $F, F^{\prime}$ be good lines with $\Delta\left(F^{\prime}\right) \subseteq \Delta(F)$. Let $F$ have ends $u_{1}, u_{2}$, and let $F^{\prime}$ have ends $u_{1}^{\prime}, u_{2}^{\prime}$, so that $u_{1}, u_{1}^{\prime}, u_{2}^{\prime}, u_{2}$ are in order in $F^{*}$.
(2) $A(F) \subseteq A\left(F^{\prime}\right)$ and $B\left(F^{\prime}\right) \subseteq B(F)$.

This is immediate since $\Delta\left(F^{\prime}\right) \subseteq \Delta(F)$.
Let $I_{1} \subseteq F^{*}$ be the support with ends $u_{1}, u_{1}^{\prime}$, and let $I_{2} \subseteq F^{*}$ have ends $u_{2}^{\prime}, u_{2}$. From (6.2), there are $q_{1}$ mutually vertex-disjoint paths of $\mu\left(I_{1}\right)$ between $V\left(\mu\left(u_{1}\right)\right)$ and $V\left(\mu\left(u_{1}^{\prime}\right)\right)$, and similarly for $I_{2}$, where the presentation has depth $q_{1}$. From (6.1)(iii), we deduce that
(3) If $|X(F)|=\left|X\left(F^{\prime}\right)\right|$ there are $|X(F)|$ mutually vertex-disjoint paths of $B(F) \cap A\left(F^{\prime}\right)$ between $X(F)$ and $X\left(F^{\prime}\right)$, each using no edge of $\Gamma$.
(4) If $F_{1}, \ldots, F_{n}$ is a sequence of good lines such that $\Delta\left(F_{i+1}\right) \subseteq \Delta\left(F_{i}\right)$ for $1 \leq i<n$, there exists $i$ with $1 \leq i<n$ such that every edge of $\Gamma \cap \Delta\left(F_{i}\right)$ is an edge of $\Gamma \cap \Delta\left(F_{i+1}\right)$.

Subproof. From (1), (2), (3) and (2.6) (with $k$ replaced by $2 q$ ), we deduce that there exists $i, i^{\prime}$ with $1 \leq i<i^{\prime} \leq n$, such that $\left|X_{i}\right|=\left|X_{i^{\prime}}\right|$ and $L \cap B_{i} \cap A_{i^{\prime}}$ uses no edge of $\Gamma$. But every edge of $B_{i} \cap A_{i^{\prime}}$ which is in $\Gamma$ is also in $L$, since $L$ is exhaustive, and so $E\left(\Gamma \cap B_{i} \cap A_{i^{\prime}}\right)=\emptyset$. Then every edge of $\Gamma \cap \Delta\left(F_{i}\right)$ is also an edge of $\Gamma \cap \Delta\left(F_{i^{\prime}}\right)$ and hence of $\Gamma \cap \Delta\left(F_{i+1}\right)$. This proves (4).

Let us say that two distinct regions $r_{1}, r_{2}$ of $\Gamma$ in $\Sigma$ touch if there is an edge $e$ of $\Gamma$ with $e \subseteq \bar{r}_{1} \cap \bar{r}_{2}$. It follows that if $r_{1}, r_{2}$ touch then $\bar{r}_{1} \cap \bar{r}_{2}=U(J)$ for some $\Sigma$-jump $J$, and if they do not touch then $\left|\bar{r}_{1} \cap \bar{r}_{2}\right| \leq 1$. In particular, the touching relation defines a graph $T$ with vertex set the set of regions of $\Gamma$ in $\Sigma$, and it is a tree. From (4), every vertex of $T$ has degree at most $n$, and every path of $T$ has at most $n$ vertices. Hence $|E(T)| \leq n^{n}=\lambda$. But $E(T)$ is in 1-1 correspondence with the $\Sigma$-jumps, and the result follows.
6.5 For all integers $p \geq 0$ and $q \geq 1$ there exists $\lambda \geq 0$ such that, if $G$ has a presentation in a disc $\Sigma$ of depth $\leq q$ and defect 2 , and there is an exhaustive vital p-linkage in $G$, then there are at most $\lambda \Sigma$-jumps.

Proof. Choose $n \geq 0$ as in (2.5) with $k$ replaced by $2 q$. Choose $\lambda^{\prime}$ so that (6.4) holds, with $p, q, \lambda$ replaced by $p+2 q, q, \lambda^{\prime}$. Let $\lambda=n\left(2 \lambda^{\prime}+1\right)$. We claim that $\lambda$ satisfies (6.5). For let $\Gamma, F_{1}^{*}, F_{2}^{*}, H_{1}, H_{2}, \mu$ be a presentation of $G$ in the disc $\Sigma$, of depth $\leq q$, and let $L$ be an exhaustive vital $p$-linkage. Let the two spaces not included in $F_{1}^{*} \cup F_{2}^{*}$ be $s_{1}^{*}$ and $s_{2}^{*}$. Let $r_{1}, \ldots, r_{t}$ be all the regions of $\Gamma$ in $\Sigma$ which are incident both with a vertex in $F_{1}^{*}$ and with a vertex in $F_{2}^{*}$, numbered in order, so that for $1 \leq i<t, r_{i}$ lies between $s_{1}^{*}$ and $r_{i+1}$, in the natural sense. For $1 \leq i \leq t$, choose $a_{i} \in V(\Gamma) \cap F_{1}^{*}$ and $b_{i} \in V(\Gamma) \cap F_{2}^{*}$ so that $r_{i}$ is incident with $a_{i}$ and $b_{i}$; and let $F_{i}$ be a good line with ends $a_{i}, b_{i}$ and with interior in $r_{i}$. Let $J_{i}$ and $K_{i}$ be the two lines in $b d(\Sigma)$ with ends $a_{i}$ and $b_{i}$, where $s_{1}^{*} \subseteq J_{i}$ and $s_{2}^{*} \subseteq K_{i}$. Then $J_{1} \subseteq J_{2} \subseteq \ldots \subseteq J_{t}$ and $K_{t} \subseteq K_{t-1} \subseteq \ldots \subseteq K_{1}$. Let $A_{i}$ be the union of $\mu\left(J_{i}\right)$ and $\Gamma \cap \Delta$, where $\Delta \subseteq \Sigma$ is the disc bounded by $F_{i} \cup J_{i}$; and define $B_{i}$ similarly using $K_{i}$ instead of $J_{i}$. Then $\left(A_{i}, B_{i}\right)$ is a separation of $G$, and $A_{i} \cap B_{i}=\mu\left(a_{i}\right) \cup \mu\left(b_{i}\right)$, as is easily seen. Since $\mu\left(a_{i}\right) \cap \mu\left(b_{i}\right)=\emptyset$, it follows that $\left|V\left(A_{i} \cap B_{i}\right)\right|=q_{1}+q_{2}$, where $|\mu(a)|=q_{j}$ for all $a \in F_{j}^{*} \cap V(\Gamma)(j=1,2)$. From (6.2), for $1 \leq i<t$, there are $q_{j}$ mutually vertex-disjoint paths of $H_{j} \cap B_{i} \cap A_{i+1}$ between $V\left(A_{i} \cap B_{i}\right)$ and $V\left(A_{i+1} \cap B_{i+1}\right)$ for $j=1$ and 2 , and since $H_{1}$ and $H_{2}$ are disjoint, it follows that there are $q_{1}+q_{2}$ mutually vertex-disjoint paths of $\left(H_{1} \cup H_{2}\right) \cap B_{i} \cap A_{i+1}$ between $V\left(A_{i} \cap B_{i}\right)$ and $V\left(A_{i+1} \cap B_{i+1}\right)$. But for $1 \leq i<t, \Gamma \cap B_{i} \cap A_{i+1}$ has an edge since $r_{i} \neq r_{i+1}$ and it belongs to $L$ since $L$ is exhaustive, and so $L \cap B_{i} \cap A_{i+1} \nsubseteq H_{1} \cup H_{2}$. From (2.5), it follows that $t \leq n$.

For $1 \leq i<t$, let $P_{i}$ be the $\Sigma$-jump with $\bar{r}_{i} \cap \bar{r}_{i}+1=U\left(P_{i}\right)$, and let $\Gamma^{\prime}=P_{1} \cup \cdots \cup P_{t-1}$. Let $R_{1}, \ldots, R_{t}$ be the regions of $\Gamma^{\prime}$ in $\Sigma$, where $r_{i} \subseteq R_{i}(1 \leq i \leq t)$. Now let us fix $i$ with $1 \leq i \leq t$. We claim that there are at most $2 \lambda^{\prime} \Sigma$-jumps $J$ with $U(J) \subseteq R_{i}$. For $j=1,2$, let $I_{j} \subseteq F_{j}^{*}$ be the support $\bar{r}_{i} \cap F_{j}^{*}$; then $\bar{r}_{j}$ is a closed disc bounded by $I_{1} \cup U\left(P_{i-1}\right) \cup I_{2} \cup U\left(P_{i}\right)$ (replacing $U\left(P_{i-1}\right)$ by $s_{1}^{*}$ if $i=1$, and replacing $U\left(P_{i}\right)$ by $s_{2}^{*}$ if $i=t$. For $j=1,2$, let $\Gamma_{j}$ be the drawing in $\Sigma$ formed by all the vertices in $V(\Gamma) \cap I_{j}$ and all the $\Sigma$-jumps $J$ with $U(J) \subseteq R_{i} \cup I_{1} \cup I_{2}$ with both ends in $I_{j}$. We claim that $\Gamma_{j}$ includes at most $\lambda^{\prime} \Sigma$-jumps. For if $\left|I_{j}\right|=1$ this is trivial, since $\Gamma_{j}$ includes no $\Sigma$-jumps. If $\left|I_{j}\right| \neq 1$ then $\Gamma_{j}, I_{j}, \mu\left(I_{j}\right)$, and the restriction of $\mu$ to $I_{j}$, is a presentation of $\Gamma_{j} \cup \mu\left(I_{j}\right)$ in a disc with depth $\leq q$ and defect 1 ; and $L \cap\left(\Gamma_{j} \cup \mu\left(I_{j}\right)\right)$ is an exhaustive vital $(p+2 q)$-linkage, and so by (6.4) it has at most $\lambda^{\prime} \Sigma$-jumps. This proves our claim that $\Gamma_{1}$ and $\Gamma_{2}$ both include at most $\lambda^{\prime} \Sigma$-jumps. Since every $\Sigma$-jump $J$ with $U(J) \subseteq R_{i} \cup I_{1} \cup I_{2}$ either has both ends in $I_{1}$ or has both ends in $I_{2}$ (because $r_{i}$ is the only region of $\Gamma$ included in $R_{i}$ incident with both $F_{1}^{*}$ and $F_{2}^{*}$ ) it follows that $R_{i}$ includes at most $2 \lambda^{\prime} \Sigma$-jumps. Counting $P_{1}, \ldots, P_{t-1}$, and using the fact that $t \leq n$, we deduce that there are at most $2 \lambda^{\prime} t+t-1 \leq \lambda \Sigma$-jumps altogether, as required.
6.6 For all integers $p \geq 0$ and $q \geq 1$ there exists $\lambda \geq 0$ such that, if $G$ has a presentation in a disc $\Sigma$ of depth $\leq q$ and defect 3 , and there is an exhaustive vital p-linkage $G$, then there are at most $\lambda$ $\Sigma$-jumps.

Proof. Choose $\lambda^{\prime} \geq 0$ so that (6.5) holds with $p, q, \lambda$ replaced by $p+2 q, q, \lambda^{\prime}$, and let $\lambda=3 \lambda^{\prime}$. We claim that $\lambda$ satisfies (6.6). For let $\Gamma, F_{1}^{*}, F_{2}^{*}, F_{3}^{*}, H_{1}, H_{2}, H_{2}, \mu$ be a presentation of $G$ in the disc $\Sigma$, of depth $\leq q$, and let there be an exhaustive vital $p$-linkage. For $i=1,2,3$, choose $v_{i} \in V(\Gamma) \cap F_{i}^{*}$ such that there is a region $r$ of $\Gamma$ in $\Sigma$ incident with $v_{1}, v_{2}$ and $v_{3}$. (It is an easy exercise to prove that this choice is possible, since $V(\Gamma) \cap b d(\Sigma) \subseteq F_{1}^{*} \cup F_{2}^{*} \cup F_{3}^{*}$.) Choose $v_{0} \in r \backslash b d(\Sigma)$, and for $i=1,2,3$ let $F_{i} \subseteq r \cup\left\{v_{i}\right\}$ be a line with ends $v_{0}$ and $v_{i}$, so that $F_{1}, F_{2}$ and $F_{3}$ are mutually disjoint except for $v_{0}$, and $F_{i} \cap b d(\Sigma)=\left\{v_{i}\right\}(i=1,2,3)$. For $i=1,2,3$ let $J_{i} \subseteq b d(\Sigma)$ be the support with ends $\left\{v_{1}, v_{2}, v_{3}\right\} \backslash\left\{v_{i}\right\}$ which does not include $F_{i}^{*}$. Let $\Delta_{1} \subseteq \Sigma$ be the closed disc bounded by $J_{1} \cup F_{2} \cup F_{3}$ and define $\Delta_{2}, \Delta_{3}$ similarly. Now

$$
\Gamma \cap \Delta_{1}, F_{2}^{*} \cap J_{1}, F_{3}^{*} \cap J_{1}, \mu\left(F_{2}^{*} \cap J_{1}\right), \mu\left(F_{3}^{*} \cap J_{1}\right)
$$

and the restriction of $\mu$ to $\left(F_{2}^{*} \cup F_{3}^{*}\right) \cap J_{1}$, is a presentation of $\Gamma \cap \Delta_{1} \cup \mu\left(F_{2}^{*} \cup J_{1}\right) \cup \mu\left(F_{3}^{*} \cup J_{1}\right)$ of depth $\leq q$ and defect 2, and this graph has an exhaustive vital $(p+2 q)$-linkage. Consequently, $\Delta_{1}$ includes at most $\lambda^{\prime} \Sigma$-jumps. Similarly so do $\Delta_{2}$ and $\Delta_{3}$, and since every $\Sigma$-jump belongs to one of these discs, it follows that there are at most $3 \lambda^{\prime}=\lambda \Sigma$-jumps altogether, as required.
6.7 For all integers $p, r \geq 0$ and $q \geq 1$ there exists $\lambda \geq 0$ such that, if $G$ has a presentation in a disc $\Sigma$ of depth $\leq q$ and defect $\leq r$, and there is an exhaustive vital $p$-linkage in $G$, then there are at most $\lambda \Sigma$-jumps.

Proof. We prove the result for all $p$ and $q$ by induction on $r$. By (6.4), (6.5), (6.6) we may assume that $r \geq 4$, and for all $p^{\prime} \geq 0$ and $q^{\prime} \geq 1$ there exists $\lambda\left(p^{\prime}, q^{\prime}\right) \geq 0$ such that, if $G$ has a presentation in a disc $\Sigma$ of depth $\leq q^{\prime}$ and defect $<r$, and there is an exhaustive vital $p^{\prime}$-linkage in $G$, then there are at most $\lambda\left(p^{\prime}, q^{\prime}\right) \Sigma$-jumps. Let $\lambda=2 \lambda(p+2 q, q)$. We claim that $\lambda$ satisfies (6.7). For let $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, H_{1}, \ldots, H_{r}, \mu$ be a presentation of $G$ in the disc $\Sigma$ of depth $\leq q$ and let there be an exhaustive vital $p$-linkage in $G$. Choose a region $r$ incident with vertices in at least three of $F_{1}^{*}, \ldots, F_{r}^{*}$, as in the proof of (6.6). Since two of these three are non-consecutive, because $r \geq 4$, it follows that there is a proper line $F \subseteq \Sigma$ with ends $a, b \in V(\Gamma)$, and with $F \cap U(\Gamma)=\{a, b\}$, such that both of the lines $J_{1}, J_{2} \subseteq b d(\Sigma)$ with ends $a$ and $b$ are disjoint from at least one of $F_{1}^{*}, \ldots, F_{r}^{*}$.

For $i=1,2$ let $\Delta_{i} \subseteq \Sigma$ be the closed disc bounded by $F \cup J_{i}$. Now $\left(\Gamma \cap \Delta_{j}\right) \cup \mu\left(J_{i}\right)$ has a presentation in $\Sigma$ with depth $\leq q$ and defect $<r$, and it has an exhaustive vital $(p+2 q)$-linkage, and so $\Delta_{j}$ includes at most $\lambda(p+2 q, q) \Sigma$-jumps, from the inductive hypothesis. But every $\Sigma$-jump belongs to one of $\Delta_{1}, \Delta_{2}$, and so there are at most $2 \lambda(p+2 q, q)=\lambda \Sigma$-jumps altogether, as required.

Proof of (6.3). We proceed by induction on $\Sigma$ and by (6.3), we may assume that $\Sigma$ is not a disc. We make the inductive hypothesis that
(1) For all integers $p, r \geq 0$ and $q \geq 1$ there exists $\lambda(p, q, r) \geq 0$ such that for every surface $\Sigma^{\prime}$, if either $\hat{\Sigma}^{\prime}$ is simpler then $\hat{\Sigma}$, or $\hat{\Sigma}^{\prime}$ is homeomorphic to $\hat{\Sigma}$ and $c\left(\Sigma^{\prime}\right)<c(\Sigma)$, the following is true. If $G^{\prime}$ is a graph with a presentation in $\Sigma^{\prime}$ of depth $\leq q$ and defect $\leq r$, and there is an exhaustive vital $p$-linkage in $G^{\prime}$, then there are at most $\lambda(p, q, r) \Sigma^{\prime}$-jumps.

Let $\lambda=\max (\lambda(p+4 q, q, r+2), 2 \lambda(p+2 q, q, r+1))$. We claim that $\lambda$ satisfies the theorem. For let $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, H_{1}, \ldots, H_{r}, \mu$ be a presentation of a graph $G$ in $\Sigma$, with depth $\leq q$.
(2) We may assume that every proper line $F \subseteq \Sigma$ with ends in $V(\Gamma)$ and with no internal point in $U(\Gamma)$ separates $\Sigma$.

Subproof. Suppose that $F \subseteq \Sigma$ is a proper line with ends $a, b \in V(\Gamma)$ and with no internal point in $U(\Gamma)$, and $F$ does not separate $\Sigma$. Let $\Sigma^{\prime}$ be obtained from $\Sigma$ by cutting along $F$. By (4.1)(i) and (4.1)(ii), either $\hat{\Sigma}^{\prime}$ is simpler than $\hat{\Sigma}$, or $\hat{\Sigma}^{\prime}$ is homeomorphic to $\hat{\Sigma}$ and $c\left(\Sigma^{\prime}\right)<c(\Sigma)$. Let $\Gamma^{\prime}$ be the drawing in $\Sigma^{\prime}$ obtained from $\Gamma$ by splitting appropriately the vertices of $\Gamma$ in $F$. Let $a \in F_{1}^{*}, b \in F_{2}^{*}$ say. Let $F_{1}^{*}$ have ends $u_{1}, u_{2}$, and let $I_{i} \subseteq F_{1}^{*}$ be the support with ends $u_{1}, a$. For each $v \in V(\mu(a))$, let $\delta_{i}(v)$ be the set of edges of $\mu\left(I_{i}\right)$ incident with $v(i=1,2)$. By splitting $v$ according to $\delta_{1}(v), \delta_{2}(v)$, for each $v \in V(\mu(a))$, and similarly splitting each $v \in V(\mu(b))$, we obtain a graph $G^{\prime}$ which has a presentation in $\Sigma^{\prime}$ (using the drawing $\Gamma^{\prime}$ ) of depth $\leq q$ and defect $\leq r+2$. But by (2.4), it follows that $G^{\prime}$ has an exhaustive vital $(p+4 q)$-linkage, and so by (1), $\Gamma^{\prime}$ has at most $\lambda(p+4 q, q, r+2)$ $\Sigma^{\prime}$-jumps. But these $\Sigma^{\prime}$-jumps are in 1-1 correspondence with the $\Sigma$-jumps of $\Gamma$, and so $\Gamma$ has at most $\lambda(p+4 q, q, r+2) \leq \lambda \Sigma$-jumps, as required. This proves (2).
(3) $c(\Sigma)=1$.

Subproof. Since $r \geq 4$, it follows that $c(\Sigma) \geq 1$. If $c(\Sigma) \geq 2$ then there is a region of $\Gamma$ incident with vertices in two different cuffs, and so there is a proper line $F$ with ends vertices of $\Gamma$ in different cuffs, and with no internal point in $U(\Gamma)$. But then $F$ does not separate $\Sigma$, contrary to (2). This proves (3).
(4) We may assume that for every proper line $F \subseteq \Sigma$ with ends in $V(\Gamma)$ and with no internal point in $U(\Gamma)$, there is a closed disc $\Delta \subseteq \Sigma$ with $F \subseteq b d(\Delta) \subseteq F \cup b d(\Sigma)$.

Subproof. By (2), $F$ separates $\Sigma$. Let $\Sigma_{1}, \Sigma_{2} \subseteq \Sigma$ be surfaces with $\Sigma_{1} \cup \Sigma_{2}=\Sigma$ and $\Sigma_{1} \cap \Sigma_{2}=F$. For $i=1,2$ let $\Gamma_{i}=\Gamma \cap \Sigma_{i}$, and let $G_{i}=\Gamma \cup \mu\left(b d(\Sigma) \cap \Sigma_{i}\right)$. Now for $i=1,2$, there is a presentation of $G_{i}$ in $\Sigma_{i}$ of depth $\leq q$ and defect $\leq r+1$, using $\Gamma_{i}$; and $L \cap G_{i}$ is an exhaustive vital $(p+2 q)$-linkage. If both $\Sigma_{1}$ and $\Sigma_{2}$ are not discs, then by (4.2)(i) and (4.2)(ii), either $\hat{\Sigma}_{i}$ is simpler than $\hat{\Sigma}$, or $\hat{\Sigma}_{i}$ is homeomorphic to $\hat{\Sigma}$ and $c\left(\Sigma_{i}\right)<c(\Sigma)$ for $i=1,2$. But then from (1), there are $\leq \lambda(p+2 q, q, r+1) \Sigma_{i}$-jumps in $\Gamma_{i}$ for $i=1,2$, and hence $\leq 2 \lambda(p+2 q, q, r+1) \leq \lambda \Sigma$-jumps in $\Gamma$, as required. Consequently we may assume that one of $\Sigma_{1}, \Sigma_{2}$ is a disc. This proves (4).

From (4), it follows in particular that every $\Sigma$-jump $J$ is homotopic in $\hat{\Sigma}$ to the lines in $b d(\Sigma)$ joining the ends of $J$. Let $R$ be the closure in $\hat{\Sigma}$ of $\hat{\Sigma} \backslash \Sigma$; thus $R \cap \Sigma$ is the unique cuff of $\Sigma$. It follows that every $O$-arc in $R \cup U(\Gamma)$ is null-homotopic in $\hat{\Sigma}$. By theorem (11.10) of [5] there is a closed disc $\Delta \subseteq \hat{\Sigma}$ with $R \cup U(\Gamma) \subseteq \Delta$. By extending $\Delta$ to a sphere and removing $R \backslash b d(R)$ from it, we deduce that $G$ has a presentation in a disc $\Sigma^{\prime}$, with depth $\leq q$ and defect $\leq r$. Then the result follows from (1), since $\lambda \geq \lambda(p+4 q, q, r+2) \geq \lambda(p, q, r)$ and $\Sigma$ is not a disc.

## 7 Presentations and tree-width

If $\mathcal{T}$ is a tangle in a graph $G$, a subgraph $A$ of $G$ is small (with respect to $\mathcal{T}$ ) if there exists $B \subseteq G$ such that $(A, B) \in \mathcal{T}$. An easy consequence of theorem (2.9) of [6] is the following (we omit the proof).
7.1 If $\mathcal{T}$ is a tangle in $G$, and $A \subseteq G$, then the following are equivalent:
(i) $A$ is small with respect to $\mathcal{T}$;
(ii) if $X$ denotes the set of vertices of $A$ incident with edges of $G$ not $A$, then $|X|<\operatorname{ord}(\mathcal{T})$, and $(A, B) \in \mathcal{T}$ where $V(B)=(V(G) \backslash V(A)) \cup X$ and $E(B)=E(G) \backslash E(A) ;$
(iii) there is a separation $(A, B)$ of order $<\operatorname{ord}(\mathcal{T})$, and $\mathcal{T}$ contains every such separation.

If $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, H_{1}, \ldots, H_{r}, \mu$ is a presentation of $G$ in $\Sigma$, and $\mathcal{T}$ is a tangle in $G$, we say that the presentation surrounds $\mathcal{T}$ if $\mu(s)$ is small for every space $s \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$.

If $\Gamma$ is a drawing in a surface $\Sigma$ such that $|V(\Gamma) \cap C| \geq 2$ for every cuff $C$, we define $\Gamma^{+}$to be the drawing in $\hat{\Sigma}$ with $U\left(\Gamma^{+}\right)=U(\Gamma) \cup b d(\Sigma)$ and $V\left(\Gamma^{+}\right)=V(\Gamma)$.
7.2 Let $\theta \geq 1$, and let $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, H_{1}, \ldots, H_{r}, \mu$ be a presentation of a graph $G$ in a surface $\Sigma$, of depth $\leq q$, and surrounding a tangle of order $\geq q \theta$. Then $\Gamma^{+}$has a tangle of order $\geq \theta$.

Proof. $\Gamma^{+}$has the same vertex set as $\Gamma$, and its edges are the edges and spaces of $\Gamma$. Let $S(\Gamma)$ be the set of spaces of $\Gamma$. For any subgraph $A$ of $\Gamma^{+}$we define $\sigma(A)$ to be the union of $A \cap \Gamma$ with all the graphs $\mu(v)(v \in V(A) \cap b d(\Sigma))$ and $\mu(s)(s \in E(A) \cap S(\Gamma))$.
(1) If $(A, B)$ is a separation of $\Gamma^{+}$then $(\sigma(A), \sigma(B))$ is a separation of $G$ of order $\leq q|V(A \cap B)|$.

Subproof. Clearly $\sigma(A) \cup \sigma(B)=G$. No edge of $G$ belongs to both $\sigma(A)$ and $\sigma(B)$, by (V1) and (V4), and so $(\sigma(A), \sigma(B))$ is a separation of $G$. We claim that

$$
V(\sigma(A) \cap \sigma(B)) \subseteq V(A \cap B) \cup \bigcup(\mu(u): u \in V(A \cap B) \cap b d(\Sigma))
$$

For let $v \in V(\sigma(A) \cap \sigma(B)) \backslash V(A \cap B)$. Since $\sigma(A) \cap \Gamma=A$ and $\sigma(B) \cap \Gamma=B$, it follows that $v \notin V(\Gamma)$; let $v \in V\left(H_{1}\right)$ say. There exists $x$ such that $v \in V(\mu(x))$, and either $x \in V(A) \cap F_{1}^{*}$ or $x \in E(A) \cap S(\Gamma)$ and $x \subseteq F_{1}^{*}$; and similarly there exists $y$ (with $B$ instead of $A$ ). Choose $x$ and $y$ as close together in $F_{1}^{*}$ as possible, in the natural sense. If $z$ lies in $F_{1}^{*}$ between $x$ and $y$, and $z \in V(\Gamma) \cup S(\Gamma)$, and $z \neq x, y$, then $z$ belongs to one of $A, B$, and $v \in V(\mu(z))$ by (V3) and (V4), contrary to our choice of $x$ and $y$. If $x \in V(\Gamma)$ and $y \in S(\Gamma)$ with one end $x$, then $x \in V(A \cap B)$ and $v \in V(\mu(x))$ as required. Finally, if $x=y \in V(\Gamma)$ then again $x \in V(A \cap B)$ and $v \in V(\mu(x))$; while if $x=y \in S(\Gamma)$ then $u \in V(A \cap B)$ and $v \in V(\mu(u))$, where $u$ is one end of $x$. This proves our claim that

$$
V(\sigma(A) \cap \sigma(B)) \subseteq V(A \cap B) \cup \bigcup(\mu(u): u \in V(A \cap B) \cap b d(\Sigma))
$$

Consequently, $|V(\sigma(A) \cap \sigma(B))| \leq q|V(A \cap B)|$. This proves (1).
Let $\mathcal{T}$ be a tangle in $G$ of order $\geq q \theta$, surrounded by the presentation. Let $\mathcal{T}^{\prime}$ be the set of all separations $(A, B)$ of $\Gamma^{+}$of order $<\theta$ such that $(\sigma(A), \sigma(B)) \in \mathcal{T}$. We claim that $\mathcal{T}^{\prime}$ is a tangle in $\Gamma^{+}$of order $\theta$. Let us verify the three axioms for a tangle.

For the first axiom, let $(A, B)$ be a separation of $\Gamma^{+}$of order $<\theta$. Then $(\sigma(A), \sigma(B))$ has order $<q \theta \leq \operatorname{ord}(\mathcal{T})$ by (1), and so one of $(\sigma(A), \sigma(B)),(\sigma(B), \sigma(A))$ belongs to $\mathcal{T}$. Hence one of $(A, B),(B, A)$ belongs to $\mathcal{T}^{\prime}$. This verifies the first axiom.

For the second, let $\left(A_{i}, B_{i}\right) \in \mathcal{T}^{\prime}(i=1,2,3)$. Then $\left(\sigma\left(A_{i}\right), \sigma\left(B_{i}\right)\right) \in \mathcal{T}(i=1,2,3)$, and so $\sigma\left(A_{1}\right) \cup \sigma\left(A_{2}\right) \cup \sigma\left(A_{3}\right) \neq G$. But

$$
\sigma\left(A_{1}\right) \cup \sigma\left(A_{2}\right) \cup \sigma\left(A_{3}\right)=\sigma\left(A_{1} \cup A_{2} \cup A_{3}\right)
$$

and $\sigma\left(\Gamma^{+}\right)=G$, and so $A_{1} \cup A_{2} \cup A_{3} \neq \Gamma^{+}$. This verifies the second axiom.
For the third, it suffices by $\left[3\right.$, theorem (2.7)] to show that if $e \in E\left(\Gamma^{+}\right)$and $K_{e}$ denotes the graph consisting of $e$ and its ends, then $\left(\Gamma^{+} \backslash e, K_{e}\right) \notin \mathcal{T}^{\prime}$, that is, $\left(\sigma\left(\Gamma^{+} \backslash e\right), \sigma\left(K_{e}\right)\right) \notin \mathcal{T}$. If $e \in E(\Gamma)$, or if $e \in S(\Gamma)$ and $e \nsubseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$ then $V\left(\sigma\left(\Gamma^{+} \backslash e\right)\right)=V(G)$, and so $\left(\sigma\left(\Gamma^{+} \backslash e\right), \sigma\left(K_{e}\right)\right) \in \mathcal{T}$, since $\mathcal{T}$ satisfies the third axiom. We assume then that $e \in S(\Gamma)$, and $e \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$. Then $\sigma\left(K_{e}\right)=\mu(e)$, and so $\left(\sigma\left(\Gamma^{+} \backslash e\right), \sigma\left(K_{e}\right)\right) \notin \mathcal{T}$ by (7.1) since $\mu(e)$ is small. This verifies the third axiom.

Hence $\mathcal{T}^{\prime}$ is a tangle in $\Gamma^{+}$of order $\theta$, as required.
The main result of this section is the following.
7.3 For every surface $\Sigma$ and all integers $p, r \geq 0$ and $q \geq 1$, there exists $\theta \geq 1$ such that, if a graph $G$ has a presentation in $\Sigma$ of depth $\leq q$, and defect $\leq r$ which surrounds a tangle of order $\geq \theta$, then $G$ has no vital p-linkage.

Proof. Choose $\lambda$ so that (6.3) holds. Choose $\theta_{1}$ so that (5.2) holds with $\Sigma, p, \theta$ replaced by $\hat{\Sigma}, 2(p+$ $\lambda), \theta_{1}$. Choose $\theta_{2}$ so that (4.6) holds, with $\Sigma, \theta^{\prime}, c, \theta$ replaced by $\hat{\Sigma}, \theta_{1}, c(\Sigma), \theta_{2}$. Let $\theta=q \theta_{2}$. We claim that $\theta$ satisfies (7.3). For let $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, H_{1}, \ldots, H_{r}, \mu$ be a presentation of $G$ in $\Sigma$, of depth $\leq q$ (we may assume its defect is exactly $r$ ), surrounding a tangle of order $\geq \theta$. Suppose that $L$ is a vital $p$-linkage in $G$. Let $\Gamma^{\prime}$ be the union of all paths in $L \cap \Gamma$ with both ends in $b d(\Sigma)$ and no internal vertex in $b d(\Sigma)$ (including one-vertex paths). Then $\Gamma^{\prime}, F_{1}^{*}, \ldots, F_{r}^{*}, H_{1}, \ldots, H_{r}, \mu$ is a presentation of $G^{\prime}=\Gamma^{\prime} \cup H_{1} \cup \ldots \cup H_{r}$ in $\Sigma$, of depth $\leq q$. Moreover, $L \cap G^{\prime}$ is a vital linkage in $G^{\prime}$, by (2.3), and it is a $p$-linkage since each component of $L$ includes at most one component of $L \cap G^{\prime}$, and it is exhaustive. From (6.3), there are at most $\lambda \Sigma$-jumps in $\Gamma^{\prime}$. Let $X$ be the set of all $v \in V(\Gamma) \cap b d(\Sigma)$ such that $\{v\}$ is the vertex set of a component of $L \cap \Gamma$. Every other component of $L \cap \Gamma$ either is a $\Sigma$-jump in $\Gamma^{\prime}$, or has an end some vertex $v \in V(\Gamma) \backslash b d(\Sigma)$ which is a terminal of $L$, by (2.2). Consequently, $L \cap(\Gamma \backslash X)$ has at most $\lambda+p$ components, and so is a vital $2(\lambda+p)$-linkage in $\Gamma \backslash X$. From (5.2), $\Gamma \backslash X$ has no tangle of order $\geq \theta_{1}$. Now $\Gamma \backslash X$ is obtained from $\Gamma^{+}$by deleting some
vertices and edges of $\Gamma^{+}$, all incident with one of $c(\Sigma)$ regions of $\Gamma^{+}$in $\hat{\Sigma}$. From (4.6), $\Gamma^{+}$has no tangle of order $\geq \theta_{2}$. From (7.2), the presentation of $G$ captures no tangle of order $\geq q \theta_{2}=\theta$, a contradiction. Thus $L$ is not a a vital $p$-linkage in $G$, as required.

## 8 Pseudo-presentations

In a presentation, the graphs $H_{1}, \ldots, H_{r}$ are disjoint. Now we want to consider a slightly more general object, in which the "last" vertices of each $H_{i}$ may equal some of the "first" vertices of the next one of $H_{1}, \ldots, H_{r}$ on the same cuff. More precisely, a pseudo-presentation of a graph $G$ in a surface $\Sigma$ is defined as follows. Let $\Gamma \subseteq G$ be a drawing in $\Sigma$ such that $|V(\Gamma) \cap C| \geq 2$ for each cuff $C$. Let $F_{1}^{*}, \ldots, F_{r}^{*}$ be mutually disjoint supports of $\Gamma$ in $\Sigma$ with $V(\Gamma) \cap b d(\Sigma) \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$. For $1 \leq j \leq r$ let $q_{j} \geq 1$ be an integer; for each $u \in V(\Gamma) \cap F_{j}^{*}$ let $\mu(u)$ be an edge-less subgraph of $G$ with $q_{j}$ vertices and with $V(\mu(u) \cap \Gamma)=\{u\}$; and for each space $s$ with $s \subseteq F_{j}^{*}$ let $\mu(s) \subseteq G$, satisfying (P1)-(P4) below. A unit is either a vertex in $V(\Gamma) \cap b d(\Sigma)$ or a space in $F_{1}^{*} \cup \ldots \cup F_{r}^{*}$.
(P1) $G=\Gamma \cup \bigcup\left(\mu\left(F_{j}^{*}\right): 1 \leq j \leq r\right) ; \Gamma$ and all the graphs $\mu(s)$ for $s \in S(\Gamma)$ and $s \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$ are mutually edge-disjoint; and if $x_{1}, x_{2}$ are units in different cuffs then $\mu\left(x_{1}\right)$ and $\mu\left(x_{2}\right)$ are mutually vertex-disjoint.
(P2) For $1 \leq j \leq r$, if $s \subseteq F_{j}^{*}$ is a space with ends $u_{1}$, $u_{2}$ then $V(\mu(s) \cap \Gamma)=\left\{u_{1}, u_{2}\right\}$ and $\mu\left(u_{1}\right), \mu\left(u_{2}\right) \subseteq \mu(s)$, and there are $q_{j}$ mutually vertex-disjoint paths of $\mu(s)$ between $V\left(\mu\left(u_{1}\right)\right)$ and $V\left(\mu\left(u_{2}\right)\right)$.
(P3) For each cuff $C$, if $x_{1}$ and $x_{2}$ are units in $C$ and $u_{1}, u_{2} \in C \cap V(\Gamma)$ are such that $x_{1}, u_{1}, x_{2}, u_{2}$ occur in order in $C$, then $\mu\left(x_{1}\right) \cap \mu\left(x_{2}\right) \subseteq \mu\left(u_{1}\right) \cup \mu\left(u_{2}\right)$.
(P4) For each cuff $C, \cap(\mu(u): u \in V(\Gamma) \cap C)$ is null.
Then we say that $\Gamma, F_{1}^{*}, \ldots, F_{4}^{*}, \mu$ is a pseudo-presentation of $G$ in $\Sigma$. Its depth is $\max \left(q_{j}: 1 \leq j \leq r\right)$, or 0 if $r=0$, and its defect is $r$. We say that the pseudo-presentation is disjointed if for each space $s$ with ends $u_{1}, u_{2}$ such that $s \nsubseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$, the graphs $\mu\left(u_{1}\right)$ and $\mu\left(u_{2}\right)$ are vertex-disjoint.
8.1 Let $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, \mu$ be a disjointed pseudo-presentation of a graph $G$ in a surface $\Sigma$. Then $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, \mu\left(F_{1}^{*}\right), \ldots, \mu\left(F_{r}^{*}\right), \mu$ is a presentation of $G$ in $\Sigma$.

Proof. Let $H_{j}=\mu\left(F_{j}^{*}\right)(1 \leq j \leq r)$. We must check that (V1)-(V4) hold (and that $\mu(s) \subseteq H_{j}$ if $s \subseteq F_{j}^{*}$ is a space, which is obvious). For (V1),

$$
G=\Gamma \cup \bigcup\left(\mu\left(F_{j}^{*}\right): 1 \leq j \leq r\right)=\Gamma \cup H_{1} \cup \ldots \cup H_{r}
$$

from (P1). To see that $H_{1}, \ldots, H_{r}$ are mutually disjoint, suppose that $v \in V\left(H_{j_{1}} \cap H_{j_{2}}\right)$ say. For $i=1,2$ let $x_{i}$ be a unit in $F_{j_{i}}^{*}$ with $v \in V\left(\mu\left(x_{i}\right)\right)$. From (P1), $x_{1}$ and $x_{2}$ belong to the same cuff $C$. We may assume that $k \leq r$, and that for $1 \leq j \leq r, F_{j}^{*} \subseteq C$ if and only if $j \leq k$, and that $F_{1}^{*}, \ldots, F_{k}^{*}$ occur in order around $C$. Let $s_{1}^{*}, \ldots, s_{k}^{*}$ be the spaces in $C$ not in $F_{1}^{*} \cup \ldots \cup F_{r}^{*}$, numbered so that if $k>1$ then $s_{j}^{*}$ has one end in $F_{j}^{*}$ and one in $F_{j+1}^{*}$ for $1 \leq j<k$, and $s_{k}^{*}$ has one end in $F_{k}^{*}$ and one in $F_{1}^{*}$. For $1 \leq j \leq k$, let $F_{j}^{*}$ have ends $a_{j}, b_{j}$, where $a_{j}$ is an end of $s_{j}^{*}$ and $b_{j}$ is an end of $s_{j-1}^{*}$ (or of $s_{k}^{*}$, if $j=1$ ). Let us write $b_{k+1}=b_{1}$ and $a_{0}=a_{k}$. Now since the pseudo-presentation is disjointed, $v$ does not belong to both $\mu\left(a_{j_{1}-1}\right)$ and $\mu\left(b_{j_{1}}\right)$; choose $u_{1} \in\left\{a_{j_{1}-1}, b_{j_{1}}\right\}$ so that $v \notin V\left(\mu\left(u_{1}\right)\right)$. Similarly choose $u_{2} \in\left\{a_{j_{1}}, b_{j_{1}+1}\right\}$ with $v \notin V\left(\mu\left(u_{2}\right)\right)$. Now $x_{1}, u_{1}, x_{2}, u_{2}$ occur in $C$ in order, contrary to (P3), since $v \in V\left(\mu\left(x_{1}\right) \cap \mu\left(x_{2}\right)\right)$ and $v \notin V\left(\mu\left(u_{1}\right) \cup \mu\left(u_{2}\right)\right)$.

This proves that $H_{1}, \ldots, H_{r}$ are disjoint. To complete the proof of (V1), we must check that for $1 \leq j \leq r, V\left(H_{j} \cap \Gamma\right)=V(\Gamma) \cap F_{j}^{*}$, and $E\left(H_{j} \cap \Gamma\right)=\emptyset$. Now $V(\Gamma) \cap F_{j}^{*} \subseteq V\left(\mu\left(F_{j}^{*}\right)\right)=V\left(H_{j}\right)$, because $u \in V(\mu(u))$ for each $u \in V(\Gamma) \cap F_{j}^{*}$. Conversely, let $u \in V\left(H_{j} \cap \Gamma\right)$. Let $x$ be a unit in $F_{j}^{*}$ with $u \in V(\mu(x))$. Since $V(\mu(x) \cap \Gamma)=\{x\}$ if $x$ is a vertex, and $V(\mu(x) \cap \Gamma)$ is the set of ends of $x$ by (P2) if $x$ is a space, it follows that either $v \in V(\Gamma) \cap F_{j}^{*}$ or $v$ is an end of some space in $F_{j}^{*}$; and so in either case, $v \in V(\Gamma) \cap F_{j}^{*}$. This proves that $V\left(H_{j} \cap \Gamma\right)=V(\Gamma) \cap F_{j}^{*}$. Finally, $E\left(H_{j} \cap \Gamma\right)=\emptyset$ because $E(\Gamma \cap \mu(S))=\emptyset$ for each space $s \subseteq F_{j}^{*}$, by ( P 1 ). This proves (V1).

Now (V2) holds by definition, and (V3) is the same as (P2), and so it only remains to verify (V4). Let $1 \leq j \leq r$, and let $s_{1}, s_{2} \subseteq F_{j}^{*}$ be spaces, and let $u \in F_{j}^{*} \cap V(\Gamma)$ lie in $F_{j}^{*}$ between $s_{1}$ and $s_{2}$. Let $s_{0}$ be a space with $s_{0} \nsubseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$, in the same cuff $C$ as $F_{j}^{*}$. (This exists since $|V(\Gamma) \cap C| \geq 2$.) Let $s_{0}$ have ends $a_{0}$ and $b_{0}$. Now $a_{0}, s_{1}, u, s_{2}$ occur in order in $C$, and so by (P3), $\mu\left(s_{1}\right) \cap \mu\left(s_{2}\right) \subseteq \mu\left(a_{0}\right) \cup \mu\left(s_{2}\right)$. Similarly, $\mu\left(s_{1}\right) \cap \mu\left(s_{2}\right) \subseteq \mu\left(b_{0}\right) \cup \mu\left(s_{2}\right)$, and so

$$
\mu\left(s_{1}\right) \cap \mu\left(s_{2}\right) \subseteq\left(\mu\left(a_{0}\right) \cap \mu\left(b_{0}\right)\right) \cap \mu\left(s_{2}\right)=\mu\left(s_{2}\right) .
$$

This proves (V4), as required.
Secondly, we wish to discuss splitting vertices in a pseudo-presentation, in order to make it disjointed. More precisely, let $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, \mu$ be a pseudo-presentation of $G$ in $\Sigma$. Let $s^{*}$ be a space with $s^{*} \nsubseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$, with ends $u_{1}, u_{2}$ say. Let $C$ be the cuff including $s^{*}$. Let $v \in V\left(\mu\left(u_{1}\right) \cap \mu\left(u_{2}\right)\right)$.

From (P4), there exists $u^{*} \in V(\Gamma) \cap C$ with $v \notin V\left(\mu\left(u^{*}\right)\right)$. Let $F_{i}$ be the support in $C$ with ends $u_{i}$ and $u^{*}$ which does not include $s^{*}(i=1,2)$. For $i=1,2$ let $\delta_{i}$ be the set of all edges $e$ incident with $v$ such that $e \in E(\mu(s))$ for some space $s \subseteq F_{i} \cap\left(F_{1}^{*} \cup \ldots \cup F_{r}^{*}\right)$. Then $\delta_{1} \cap \delta_{2}=\emptyset$, for by (P2) there is only one space $s \subseteq C$ with $e \in E(\mu(s))$; and $\delta_{1} \cup \delta_{2}$ is the set of all edges of $G$ incident with $v$, because by (P1) $e$ is an edge of $\mu(s)$ for some space $s \subseteq C \cap\left(F_{1}^{*} \cup \ldots \cup F_{r}^{*}\right)$. Let $G^{\prime}$ be obtained from $G$ by splitting $v$ according to $\delta_{1}, \delta_{2}$, and let the two new vertices of $G^{\prime}$ be $v_{1}, v_{2}$ where the edges in $\delta_{i}$ are incident with $v_{i}(i=1,2)$. For $i=1,2$, and for each subgraph $A$ of $G$ with $v \in V(A)$, let $\sigma_{i}(A)$ be the graph with the same set of edges as $A$, and with vertex set $(V(A) \backslash\{v\}) \cup\left\{v_{i}\right\}$, with the same incidence relation as $A$ except that the edges of $A$ that are incident with $v$ in $A$ are incident with $v_{i}$ in $\sigma_{i}(A)$. Then $\sigma_{i}(A)$ is a subgraph of $G^{\prime}$ provided that $\delta_{i}$ contains all edges of $A$ incident with $v$. Define $\mu^{\prime}$ by:

$$
\begin{aligned}
\mu^{\prime}(u) & =\mu(u) \text { if } v \in V(\Gamma) \cap b d(\Sigma) \text { and } v \notin V(\mu(u)) \\
\mu^{\prime}(u) & =\sigma_{i}(\mu(u)) \text { if } v \in V(\Gamma) \cap F_{i} \text { and } v \in V(\mu(u))(i=1,2) \\
\mu^{\prime}(s) & =\mu(s) \text { if } s \text { is a space with } s \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*} \text { and } v \notin V(\mu(s)) \\
\mu^{\prime}(s) & =\sigma_{i}(\mu(s)) \text { if } s \text { is a space with } s \subseteq\left(F_{1}^{*} \cup \ldots \cup F_{r}^{*}\right) \cap F_{i} \text { and } v \in V(\mu(s))(i=1,2) .
\end{aligned}
$$

$8.2 \Sigma, F_{1}^{*}, \ldots, F_{r}^{*}, \mu^{\prime}$ is a pseudo-presentation of $G^{\prime}$.

Proof. Since $v \in V\left(\mu\left(u_{1}\right) \cap \mu\left(u_{2}\right)\right)$ it follows that $v \neq u_{1}, u_{2}$, and so $v \notin V(\Gamma)$. Consequently $\Gamma \subseteq G^{\prime}$. Let us check that $\mu^{\prime}(x) \subseteq G^{\prime}$, for each unit $x$. If $x$ is a vertex this is clear, so let $x$ be a space with $x \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$. If $v \notin V(\mu(x))$ then $\mu^{\prime}(x)=\mu(x) \subseteq G^{\prime}$ as required. We assume then that $v \in V(\mu(x))$, and $x \subseteq F_{1}$ say. Then $\mu^{\prime}(x)=\sigma_{1}(\mu(x))$, and every edge of $\mu(x)$ incident with $v$ belongs to $\delta_{1}$, by definition of $\delta_{1}$. Consequently $\mu^{\prime}(x) \subseteq G^{\prime}$, as required.

We must verify (P1)-(P4). For (P1), we observe that

$$
E\left(G^{\prime}\right)=E(G)=E\left(\Gamma \cup \bigcup\left(\mu\left(F_{j}^{*}\right): 1 \leq j \leq r\right)\right)=E\left(\Gamma \cup \bigcup\left(\mu^{\prime}\left(F_{j}^{*}\right): 1 \leq j \leq r\right)\right)
$$

and

$$
\begin{aligned}
V\left(G^{\prime}\right) & =(V(G) \backslash\{v\}) \cup\left\{v_{1}, v_{2}\right\}=\left(V\left(\Gamma \cup \bigcup\left(\mu\left(F_{j}^{*}\right): 1 \leq j \leq r\right)\right) \backslash\{v\}\right) \cup\left\{v_{1}, v_{2}\right\} \\
& \subseteq V(\Gamma) \cup \bigcup\left(\mu^{\prime}\left(F_{j}^{*}\right): 1 \leq j \leq r\right)
\end{aligned}
$$

since $v_{1} \in \mu^{\prime}\left(F_{1}^{*}\right)$ and $v_{2} \in \mu^{\prime}\left(F_{2}^{*}\right)$. The remainder of (P1) is clear and so (P1) holds.

For $(\mathrm{P} 2)$, let $s \subseteq F_{j}^{*}$ be a space with ends $a, b$ say. Certainly $V\left(\mu^{\prime}(s) \cap \Gamma\right)=V(\mu(s) \cap \Gamma)=\{a, b\}$. To see that $\mu^{\prime}(a) \subseteq \mu^{\prime}(s)$ we argue as follows. If $v \notin V(\mu(a))$ then

$$
\mu^{\prime}(a)=\mu(a) \subseteq \mu(s) \backslash v=\mu^{\prime}(s) \backslash v \subseteq \mu^{\prime}(s)
$$

as required. We assume then that $v \in V(\mu(a))$, and hence $v \in V(\mu(s))$. Thus $s \subseteq F_{1}$ or $s \subseteq F_{2}$, say $s \subseteq F_{1} ;$ and so $a \in F_{1}$. Hence

$$
\mu^{\prime}(a)=\sigma_{1}(\mu(a)) \subseteq \sigma_{1}(\mu(s))=\mu^{\prime}(s)
$$

as required. This verifies the second assertion of (P2). The third assertion follows because there is an isomorphism from $\mu(s)$ to $\mu^{\prime}(s)$ mapping $\mu(a)$ to $\mu^{\prime}(a)$ and $\mu(b)$ to $\mu^{\prime}(b)$.

For (P3), let $x_{1}, a, x_{2}, b$ be units of a cuff $C$ in order, where $a, b \in V(\Gamma)$. We must show that

$$
\mu^{\prime}\left(x_{1}\right) \cap \mu^{\prime}\left(x_{2}\right) \subseteq \mu^{\prime}(a) \cup \mu^{\prime}(b)
$$

Since

$$
E\left(\mu^{\prime}\left(x_{1}\right) \cap \mu^{\prime}\left(x_{2}\right)\right)=E\left(\mu\left(x_{1}\right) \cap \mu\left(x_{2}\right)\right) \subseteq E(\mu(a) \cup \mu(b))=E\left(\mu^{\prime}(a) \cup \mu^{\prime}(b)\right)
$$

it suffices to show that every vertex of $\mu^{\prime}\left(x_{1}\right) \cap \mu^{\prime}\left(x_{2}\right)$ is a vertex of $\mu^{\prime}(a) \cup \mu^{\prime}(b)$. Let $w \in V\left(\mu^{\prime}\left(x_{1}\right) \cap\right.$ $\left.\mu^{\prime}\left(x_{2}\right)\right)$. If $w \neq v_{1}, v_{2}$ then

$$
w \in V\left(\mu\left(x_{1}\right) \cap \mu\left(x_{2}\right)\right) \subseteq V(\mu(a) \cup \mu(b))
$$

and since $w \neq v$ it follows that $w \in V\left(\mu^{\prime}(a) \cup \mu^{\prime}(b)\right)$ as required. We may assume then that $w=v_{1}$ say. Thus $v_{1} \in V\left(\mu^{\prime}\left(x_{1}\right) \cap \mu^{\prime}\left(x_{2}\right)\right)$. From the definition of $\mu^{\prime}\left(x_{1}\right)$ and $\mu^{\prime}\left(x_{2}\right)$ it follows that $v \in \mu\left(x_{1}\right) \cap \mu\left(x_{2}\right)$ and $x_{1}, x_{2}$ belong to $F_{1}$. Since $x_{1}, a, x_{2}, b$ occur in order in $C$ we may assume that $a \in F_{1}$ and lies in $F_{1}$ between $x_{1}$ and $x_{2}$. Since $x_{1}, a, x_{2}, u^{*}$ occur in order in $C$, it follows that

$$
v \in V\left(\mu\left(x_{1}\right) \cap \mu\left(x_{2}\right)\right) \subseteq V\left(\mu(a) \cup \mu\left(u^{*}\right)\right)
$$

and since $v \notin V\left(\mu\left(u^{*}\right)\right)$ we deduce that $v \in V(\mu(a))$. But $a \in F_{1}$, and $\mu^{\prime}(a)=\sigma_{1}(\mu(a))$, and so $v_{1} \in V\left(\mu^{\prime}(a)\right)$, as required. This proves (P3).

For (P4), suppose that $w \in V\left(\mu^{\prime}(u)\right)$ for every $u \in V(\Gamma) \cap C^{\prime}$ for some cuff $C^{\prime}$. If $w \neq v_{1}, v_{2}$ then $w \in \mu(a)$ for all $u \in V(\Gamma) \cap C^{\prime}$, and so $w \in \bigcap\left(\mu(u): u \in V(\Gamma) \cap C^{\prime}\right)$, contrary to the truth of (P4) for $\mu$. Thus we may assume that $w=v_{1}$ say, and hence $C^{\prime}=C$. But $v_{1} \notin V\left(\mu\left(u^{*}\right)\right)=V\left(\mu^{\prime}\left(u^{*}\right)\right)$, a contradiction. This proves ( P 4 ), and therefore completes the proof of (8.2).

Now let $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, \mu$ be a pseudo-presentation of $G$, and let $\mathcal{T}$ be a tangle in $G$. We say the pseudo-presentation surrounds $\mathcal{T}$ if $\mu(s)$ is small for every space $s \in F_{1}^{*} \cup \ldots \cup F_{r}^{*}$.
8.3 With notation as in (8.2), suppose that $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, \mu$ is a pseudo-presentation of depth $\leq q$, and surrounds a tangle $\mathcal{T}$ in $G$ of order $\theta \geq 2 q+3$. Then $\Gamma, F_{1}^{*}, \ldots, F_{r}^{*}, \mu^{\prime}$ surrounds a tangle in $G^{\prime}$ of order $\theta-1$.

Proof. Let $\mathcal{T}^{\prime}$ be the tangle of order $\theta-1$ in $G^{\prime}$ induced by $\mathcal{T} \backslash\{v\}$. (This exists, from (3.2) and (3.4).) Let $s \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$ be a space, and choose $B \subseteq G$ minimal such that $(\mu(s), B)$ is a separation of $G$. By (7.1), $(\mu(s), B) \in \mathcal{T}$ since $\mu(s)$ is small. Let $w \in V(\mu(s) \cap B)$; we claim that $w \in V(\mu(a) \cup \mu(b))$, where $s$ has ends $a$ and $b$. For if $w=a$ or $b$ this is true, and we assume not. By (P2), $w \notin V(\Gamma)$. Since $u \in V(B)$ it follows from the minimality of $B$ that some edge $e$ of $G$ not in $\mu(s)$ is incident with $w$, and $e \notin E(\Gamma)$ since $w \notin V(\Gamma)$. Choose a space $s^{\prime}$ with $e \in E\left(\mu\left(s^{\prime}\right)\right)$. Then $s^{\prime} \neq s$, and so $s, a, s^{\prime}, b$ are in order in the cuff containing them (this exists, by (P1)). By (P3),

$$
w \in V\left(\mu(s) \cap \mu\left(s^{\prime}\right)\right) \subseteq V(\mu(a) \cup \mu(b))
$$

as claimed. We have proved then that $V(\mu(s) \cap B) \subseteq V(\mu(a) \cup \mu(b))$. Hence $(\mu(s), B)$ has order $\leq 2 q \leq \theta-2$.

Let $A_{1}$ be the subgraph of $G$ with vertex set $V(\mu(s)) \cup\{v\}$ and edge set $E(\mu(s))$; and let $B_{1}$ have vertex set $V(B) \cup\{v\}$ and edge set $E(B)$. By theorem (2.9)(iii) of $[6],\left(A_{1}, B_{1}\right) \in \mathcal{T}$, since $(\mu(s), B)$ has order $\leq \theta-2$. Hence $\left(A_{1} \backslash v, B_{1} \backslash v\right) \in \mathcal{T} \backslash v$. Let $A_{2}=\mu^{\prime}(s)$, and let $B_{2} \subseteq G^{\prime}$ be minimal such that $\left(A_{2}, B_{2}\right)$ is a separation of $G^{\prime}$. Then $\left(A_{2}, B_{2}\right)$ has order $\leq 2 q$. But $A_{2} \cap(G \backslash v)=A_{1} \backslash v$, and so $\left(A_{2} \cap(G \backslash v), B_{2} \cap(G \backslash v)\right) \in \mathcal{T} \backslash v$ by theorem (2.9)(iii) of [6], since $\left(A_{1} \backslash v, B_{1} \backslash v\right) \in \mathcal{T} \backslash v$ and $\mathcal{T} \backslash v$ has order $\geq 2$. From the definition of $\mathcal{T}^{\prime}$ it follows that $\left(A_{2}, B_{2}\right) \in \mathcal{T}^{\prime}$, and so $\mu^{\prime}(s)$ is small with respect to $\mathcal{T}^{\prime}$, as required.

The main result of this section is the following.
8.4 For every surface $\Sigma$ and all integers $p, r \geq 0$ and $q \geq 1$, there exists $\theta \geq 1$ such that, if a graph $G$ has a pseudo-presentation in $\Sigma$ of depth $\leq q$ and defect $\leq r$ which surrounds a tangle of order $\geq \theta$, then $G$ has no vital p-linkage.

Proof. Choose $\theta^{\prime} \geq 2 q+2$ so that (7.3) holds, with $\Sigma, p, q, r$ replaced by $\Sigma, p+2 q r, q, r$. Let $\theta=\theta^{\prime}+q r$. We claim that $\theta$ satisfies (8.4). For suppose that $G$ has a pseudo-presentation in $\Sigma$ of
depth $\leq q$ and defect $\leq r$ which surrounds a tangle of order $\geq \theta$. For each space $s \nsubseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$ with ends $u_{1}, u_{2}$ and for each $v \in V\left(\mu\left(u_{1}\right) \cap \mu\left(u_{2}\right)\right)$, split $v$ as discussed earlier in this section. After at most $q r$ splittings we obtain a graph $G^{\prime}$ with a disjointed pseudo-presentation in $\Sigma$ of depth $\leq q$ and defect $\leq r$, which by (8.3) surrounds a tangle of order $\geq \theta-q r=\theta^{\prime}$, since $\theta^{\prime}+1 \geq 2 q+3$. By (8.1), $G^{\prime}$ has a presentation in $\Sigma$ of depth $\leq q$ and defect $\leq r$ which surrounds a tangle of order $\geq \theta^{\prime}$. By (7.3), $G^{\prime}$ has no vital $(p+2 q r)$-linkage, from the choice of $\theta^{\prime}$. But $G^{\prime}$ is obtained from $G$ by splitting $\leq q r$ vertices, and so by (2.4) $G$ has no vital $p$-linkage, as required.

## 9 Paintings and portraits

In this section we derive a modification of (8.4) appropriate for applying the results of [9, 10]. A painting $\Gamma$ in a surface $\Sigma$ is a pair $(U, V)$, where $U \subseteq \Sigma$ is closed and $V \subseteq U$ is finite, satisfying
(i) $U \backslash V$ has only finitely many connected components, called cells
(ii) for each cell $c$, its closure $\bar{c}$ is a closed disc, and $\tilde{c} \subseteq b d(\bar{c})$ (where $\tilde{c}$ denotes $\bar{c} \backslash c$ ) and $|\tilde{c}|=2$ or 3
(iii) $b d(\Sigma) \subseteq U$
(iv) for each cell $c$, if $c \cap b d(\Sigma) \neq \emptyset$ (that is, $c$ is a border cell) then $|\tilde{c}|=2$ and $\bar{c} \cap b d(\Sigma)$ is a line with ends the two members of $\tilde{c}$.
(This differs very slightly from the definition in [10]. In that paper it was convenient to allow cells $c$ with $|\tilde{c}|=0$ or 1 , but we no longer need such cells.) The set of cells of $\Gamma$ is denoted by $C(\Gamma)$, and we write $U=U(\Gamma), V=V(\Gamma)$. A cell which is not a border cell is called an internal cell.

Let $G$ be a graph. We say that a pair $\Gamma, \alpha$ is a portrait of $G$ in $\Sigma$ (this is closely connected with the "portrayal" of [10]) if
(R1) $\Gamma$ is a painting in $\Sigma$ and $V(\Gamma) \subseteq V(G)$, and $\alpha$ is a function with domain $(V(\Gamma) \cap b d(\Sigma)) \cup C(\Gamma)$.
(R2) For each $c$ of $\Gamma, \alpha(c) \subseteq G$ and $V(\alpha(c)) \cap V(\Gamma)=\tilde{c}$.
(R3) $G=\bigcup(\alpha(c): c \in C(\Gamma))$, and $E\left(\alpha\left(c_{1}\right) \cap \alpha\left(c_{2}\right)\right)=\emptyset$ for all distinct cells $c_{1}, c_{2}$.
(R4) For each $v \in V(\Gamma) \cap b d(\Sigma), \alpha(v)$ is an edge-less subgraph of $G$ and $V(\alpha(v) \cap V(\Gamma)=\{v\}$.
(R5) For each cuff $C$ there is an integer $q(C) \geq 1$ such that $|V(\alpha(v))|=q(C)$ for all $v \in V(\Gamma) \cap C$.
(R6) For each border cell $c$ with $\tilde{c}=\{u, v\}, \alpha(u)$ and $\alpha(v)$ are subgraphs of $\alpha(c)$, and either
(i) there are $|V(\alpha(u))|$ mutually vertex-disjoint paths of $\alpha(c)$ between $V(\alpha(u))$ and $V(\alpha(v))$, that is, $c$ is "linked", or
(ii) there is a cell $c^{\prime}$ with $\left|\tilde{c}^{\prime}\right|=3$ and $u, v \in \tilde{c}^{\prime}$.
(R7) If $c_{1}, c_{2} \in C(\Gamma)$ are distinct, then $V\left(\alpha(c) \cap \alpha\left(c^{\prime}\right)\right)=\tilde{c}_{1} \cap \tilde{c}_{2}$ unless $c_{1}$ and $c_{2}$ border the same cuff (that is, unless $c_{1} \cap C \neq \emptyset \neq c_{2} \cap C$ for some cuff $C$ ).
(R8) If $c_{1}, c_{2} \in C(\Gamma)$ border a cuff $C$, and $u_{1}, u_{2} \in V(\Gamma) \cap C$ and $c_{1}, u_{1}, c_{2}, u_{2}$ are in order around $C$, then $\alpha\left(c_{1}\right) \cap \alpha\left(c_{2}\right) \subseteq \alpha\left(u_{1}\right) \cup \alpha\left(u_{2}\right)$.
(R9) If $c \in C(\Gamma)$ and $|\tilde{c}|=3$, then $\alpha(c)$ cannot be drawn in a disc so that the three members of $\tilde{c}$ are drawn in the boundary of the disc.
(R10) For each cuff $C, \bigcap(\alpha(u): u \in V(\Gamma) \cap C)$ is null.
Its depth is the maximum of $q(C)$, taken over all cuffs $C$ (or 0 if $b d(\Sigma)=\emptyset)$.)
9.1 If $\Gamma, \alpha$ is a portrait in a surface $\Sigma$ of a graph $G$, and $L$ is a vital linkage in $G$, then for every cell $c$ of $\Gamma$ which is not a border cell, either $V(\alpha(c)) \backslash \tilde{c}$ contains a terminal of $L$, or $\alpha(c)$ can be drawn in a disc with the members of $\tilde{c}$ drawn in the boundary.

Proof. Let $c \in C(\Gamma)$ be an internal cell such that $V(\alpha(c)) \backslash \tilde{c}$ contains no terminal of $L$. We must prove that $\alpha(c)$ can be drawn in a disc with $\tilde{c}$ in the boundary. If $V(\alpha(c))=\tilde{c}$ this is clear, and we therefore may assume that $V(\alpha(c)) \neq \tilde{c}$. Since by (R2) $\tilde{c} \subseteq V(\alpha(c))$, there is a vertex in $V(\alpha(c)) \backslash \tilde{c}$. Since $V(L)=V(G)$, there is a component $P$ of $L$ with $V(P \cap(\alpha(c))) \nsubseteq \tilde{c}$. Since $V(\alpha(c)) \backslash \tilde{c}$ contains no end of $P$, and $c$ is internal, it follows from (R7) that $|V(P) \cap \tilde{c}| \geq 2$; and so $P$ is the only component of $L$ with a vertex in $V(\alpha(c)) \backslash \tilde{c}$, since $|\tilde{c}| \leq 3$. Consequently, $V(\alpha(c)) \backslash \tilde{c} \subseteq V(P)$. But $L$ is vital, and so any two vertices of $P \cap \alpha(c)$ that are adjacent in $\alpha(c)$ are also adjacent in $P$. Hence either $\alpha(c)$ is a path with both ends in $\tilde{c}$, or $\alpha(c) \backslash v$ is a path with both ends in $\tilde{c}$, for some $v \in \tilde{c}$. In either case $\alpha(c)$ can be drawn in a disc with all the members of $\tilde{c}$ drawn in the boundary, as required.

If $\mathcal{T}$ is a tangle in $G$, a portrait $\Gamma, \alpha$ of $G$ in $\Sigma$ surrounds $\mathcal{T}$ if $\alpha(c)$ is small for each $c \in C(\Gamma)$.
9.2 For every surface $\Sigma$, and all integers $p \geq 0$ and $q \geq 1$, there exists $\theta \geq 1$ such that, if a graph $G$ has a portrait in $\Sigma$ of depth $\leq q$ which surrounds a tangle of order $\geq \theta$, then $G$ has no vital p-linkage.

Proof. Let $n=3 p+2 q(3 p+c(\Sigma))$. Choose $\theta^{\prime}>2 q$ so that (8.4) holds, with $\Sigma, p, q, r, \theta$ replaced by $\Sigma, p+n, q, r, \theta^{\prime}$. Let $\theta=\theta^{\prime}+n$. We claim that $\theta$ satisfies (9.2). For let $\Gamma, \alpha$ be a portrait in $\Sigma$ of a graph $G$, with depth $\leq q$, surrounding a tangle $\mathcal{T}$ of order $\geq \theta$. Suppose that $L$ is a vital $p$-linkage in $G$. Let $\mathcal{A}_{1}$ be the set of all internal cells $c$ such that $V(\alpha(c)) \backslash \tilde{c}$ contains a terminal of $L$. Since the sets $V(\alpha(c)) \backslash \tilde{c}\left(c \in \mathcal{A}_{1}\right)$ are mutually disjoint, by (R7), it follows that $\left|\mathcal{A}_{1}\right| \leq p$. By (9.1) and (R9), $\mathcal{A}_{1}$ contains every cell of $\Gamma$ with $|\tilde{c}|=3$. By (R6), there are $\leq 3\left|\mathcal{A}_{1}\right|$ border cells that are not linked. Let $\mathcal{A}_{2} \subseteq C(\Gamma)$ be minimal such that $\mathcal{A}_{2}$ contains all border cells that are not linked, and contains at least one cell bordering each cuff. Thus, $\left|\mathcal{A}_{2}\right| \leq 3 p+c(\Sigma)$.

For each internal cell $c \in C(\Gamma) \backslash \mathcal{A}_{1}$, there is a drawing of $\alpha(c)$ in the closed disc $\bar{c}$ with the vertices in $\tilde{c}$ representing themselves, by (9.1), and this drawing can be chosen so that it meets $b d(\bar{c})$ only in $\tilde{c}$. We may therefore assume, to simplify the notation, that $\alpha(c)$ is such a drawing in $\bar{c}$ for each internal cell $c \in C(\Gamma) \backslash \mathcal{A}_{1}$. Let $\Gamma^{\prime}$ be the drawing formed by the vertices in $V(\Gamma)$ and the union of the drawings $\alpha(c)$ over all internal $c \in C(\Gamma) \backslash \mathcal{A}_{1}$. Then $\Gamma^{\prime}$ is a drawing in $\Sigma$, and there is a 1-1 correspondence between the spaces of $\Gamma^{\prime}$ and the border cells of $\Gamma$.

Let $G^{\prime}$ be the subgraph of $G$ formed by the vertices in $V(\Gamma)$, the graphs $\alpha(u)\left(u \in V\left(\Gamma^{\prime}\right) \cap b d(\Sigma)\right)$ and the graphs $\alpha(c)\left(c \in C(\Gamma) \backslash\left(\mathcal{A}_{1} \cup \mathcal{A}_{2}\right)\right)$. Then $\Gamma^{\prime} \subseteq G^{\prime}$. Now $V\left(\Gamma^{\prime}\right) \cap b d(\Sigma)=V(\Gamma) \cap b d(\Sigma) ;$ define $\mu(u)=\alpha(u)$ for each $u \in V\left(\Gamma^{\prime}\right) \cap b d(\Sigma)$. Let $F_{1}^{*}, \ldots, F_{r}^{*}$ be the connected components of $b d(\Sigma) \backslash \bigcup\left(c: c \in \mathcal{A}_{2}\right)$. Then $F_{1}^{*}, \ldots, F_{r}^{*}$ are all supports of $\Gamma^{\prime}$ since $\mathcal{A}_{2}$ contains at least one cell bordering each cuff; they are mutually disjoint, and $V\left(\Gamma^{\prime}\right) \cap b d(\Sigma) \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$. Moreover, $r=\left|\mathcal{A}_{2}\right| \leq 3 p+c(\Sigma)$. For each space $s$ of $\Gamma^{\prime}$ with $s \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$, let $\mu(s)=\alpha(c)$, where $c$ is the cell of $\Gamma$ with $c \cap b d(\Sigma)=s$.
(1) $\Gamma^{\prime}, F_{1}^{*}, \ldots, F_{r}^{*}, \mu$ is a pseudo-presentation of $G^{\prime}$.

Subproof. Certainly $\left|V\left(\Gamma^{\prime}\right) \cap C\right| \geq 2$ for each cuff $C$, because $\Gamma$ is a painting and $V(\Gamma) \subseteq V\left(\Gamma^{\prime}\right)$. We must verify (P1)-(P4). First let us verify (P1). Now

$$
\begin{aligned}
G^{\prime} & =\Gamma^{\prime} \cup \bigcup\left(\alpha(c): c \in C(\Gamma) \backslash \mathcal{A}_{2} \text { and } c \text { is a border cell }\right) \cup \bigcup\left(\alpha(u): u \in V\left(\Gamma^{\prime}\right) \cap b d(\Sigma)\right) \\
& =\Gamma^{\prime} \cup \mu\left(F_{1}^{*}\right) \cup \ldots \cup \mu\left(F_{r}^{*}\right) .
\end{aligned}
$$

By (R3), $E\left(\mu(s) \cap \mu\left(s^{\prime}\right)\right)=\emptyset$ if $s$ and $s^{\prime}$ are distinct spaces, since each border cell of $\Gamma$ includes only one space of $\Gamma^{\prime}$. Since each edge of $\Gamma^{\prime}$ is an edge of $\alpha(c)$ for some internal cell $c$, it follows from (R3) again that $E\left(\Gamma^{\prime} \cap \mu(s)\right)=\emptyset$ for each space $s \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$. Finally, let $x_{1}, x_{2}$ be units of $\Gamma$ in
different cuffs. Then there are border cells $c_{1}, c_{2}$ of $\Gamma$ bordering different cuffs with $\mu\left(x_{i}\right) \subseteq \alpha\left(c_{i}\right)$, by (R6) and condition (iii) in the definition of a painting. By condition (iv) in the definition of a painting, $\tilde{c} \cap \tilde{c}^{\prime}=\emptyset$, and so by (R7), $\alpha\left(c_{1}\right) \cap \alpha\left(c_{2}\right)$ is null. Consequently, $\mu\left(x_{1}\right) \cap \mu\left(x_{2}\right)$ is null. This proves (P1).

For (P2), let $1 \leq j \leq r$ and let $s \subseteq F_{j}^{*}$ be a space of $\Gamma^{\prime}$, with ends $u_{1}, u_{2}$. Let $c$ be the cell of $\Gamma$ with $c \cap b d(\Sigma)=s$; then $\tilde{c}=\left\{u_{1}, u_{2}\right\}$. Since $s \subseteq F_{j}^{*}$ it follows that $c \notin \mathcal{A}_{2}$, and so $c$ is linked. Consequently, (P2) holds, taking $q_{j}=q(C)$ where $C$ is the cuff including $F_{j}^{*}$ and (see (R5)) $q(C)$ is the common cardinality of all the sets $V(\alpha(v))(v \in V(\Gamma) \cap C)$.

For (P3), let $C$ be a cuff, let $x_{1}, x_{2}$ be units of $\Gamma^{\prime}$ in $C$, and let $u_{1}, u_{2} \in C \cap V(\Gamma)$ so that $x_{1}, u_{1}, x_{2}, u_{2}$ are in order in $C$. We must show that $\mu\left(x_{1}\right) \cap \mu\left(x_{2}\right) \subseteq \mu\left(u_{1}\right) \cup \mu\left(u_{2}\right)$. If one of $x_{1}, x_{2}$ equals one of $u_{1}, u_{2}$ then the inclusion is trivial, and so we assume that $x_{1}, x_{2} \neq u_{1}, u_{2}$. For $i=1,2$, let $c_{i}$ be a border cell of $\Gamma$ with $c_{i} \cap b d(\Sigma)=x_{i}$ if $x_{i}$ is a space of $\Gamma^{\prime}$, and $x_{i} \in \tilde{c}_{i}$ if $x_{i} \in V\left(\Gamma^{\prime}\right)$. By (R6),

$$
\mu\left(x_{i}\right)=\alpha\left(x_{i}\right) \subseteq \alpha\left(c_{i}\right)(i=1,2)
$$

and so $\mu\left(x_{1}\right) \cap \mu\left(x_{2}\right) \subseteq \alpha\left(c_{1}\right) \cap \alpha\left(c_{2}\right)$. But $c_{1}, u_{1}, c_{2}, u_{2}$ are in order, and so by (R8),

$$
\alpha\left(c_{1}\right) \cap \alpha\left(c_{2}\right) \subseteq \alpha\left(u_{1}\right) \cup \alpha\left(u_{2}\right)=\mu\left(u_{1}\right) \cup \mu\left(u_{2}\right)
$$

This proves (P3).
But (P4) is immediate from (R10). This completes the proof of (1).
For each internal $c \in C(\Gamma)$, let $B(c) \subseteq G$ be such that $(\alpha(c), B(c))$ is a separation of $G$ and $V(\alpha(c) \cap B(c))=\tilde{c}$. (This is possible by (R7).) For each border cell $c$, let $B(c) \subseteq G$ be such that $(\alpha(c), B(c))$ is a separation of $G$ and $\alpha(c) \cap B(c)=\mu\left(u_{1}\right) \cup \mu\left(u_{2}\right)$, where $\tilde{c}=\left\{u_{1}, u_{2}\right\}$. (This is possible by (R7) and (R8).)
(2) $G^{\prime}=G \cap \bigcap\left(B(c): c \in \mathcal{A}_{1} \cup \mathcal{A}_{2}\right)$.

Subproof. Certainly $G^{\prime} \subseteq B(c)$ for each $c \in \mathcal{A}_{1} \cup \mathcal{A}_{2}$. For the converse inclusion, if $e \in E(G)$ is an edge of $B(c)$ for all $c \in \mathcal{A}_{1} \cup \mathcal{A}_{2}$, then by (R3) $e$ is an edge of $\alpha(c)$ for some $c \in C(\Gamma) \backslash\left(\mathcal{A}_{1} \cup \mathcal{A}_{2}\right)$, and so $e \in E\left(G^{\prime}\right)$. If $v \in V(G)$ is a vertex of $B(c)$ for all $c \in \mathcal{A}_{1} \cup \mathcal{A}_{2}$, choose $c \in C(\Gamma)$ with $v \in V(\alpha(c))$. If $c \in C(\Gamma) \backslash \mathcal{A}_{1} \cup \mathcal{A}_{2}$ then $v \in V\left(G^{\prime}\right)$ as required. If $c \in \mathcal{A}_{1}$ then $v \in \tilde{c}$ because $v \in V(B(c) \cap \alpha(c))=\tilde{c}$, and so $v \in V(\Gamma) \subseteq V\left(G^{\prime}\right)$ as required. If $c \in \mathcal{A}_{2}$, then $v \in V\left(\mu\left(u_{1}\right) \cup \mu\left(u_{2}\right)\right)$ where $\tilde{c}=\left\{u_{1}, u_{2}\right\}$ for the same reason, and so again $v \in V\left(G^{\prime}\right)$. This proves (2).

Let $A_{0}=\bigcup\left(\alpha(c): c \in \mathcal{A}_{1} \cup \mathcal{A}_{2}\right)$. From (2), $\left(A_{0}, G^{\prime}\right)$ is a separation of $G$. Since every vertex of $V\left(A_{0} \cap G^{\prime}\right)$ belongs to $V(\alpha(c) \cap B(c))$ for some $c \in \mathcal{A}_{1} \cup \mathcal{A}_{2}$, it follows that ( $A_{0}, G^{\prime}$ ) has order

$$
\leq 3\left|\mathcal{A}_{1}\right|+2 q\left|\mathcal{A}_{2}\right| \leq 3 p+2 q(3 p+c(\Sigma))=n .
$$

We deduce from (3.5) that
(3) There is a tangle $\mathcal{T}^{\prime}$ in $G^{\prime}$ of order $\geq \theta-n=\theta^{\prime}$, such that $\left(A \cap G^{\prime}, B \cap G^{\prime}\right) \in \mathcal{T}^{\prime}$ for every $(A, B) \in \mathcal{T}$ of order $<\theta^{\prime}$.
(4) The pseudo-presentation $\Gamma^{\prime}, F_{1}^{*}, \ldots, F_{r}^{*}, \mu$ of $G^{\prime}$ surrounds $\mathcal{T}^{\prime}$.

Subproof. Let $s$ be a space of $\Gamma^{\prime}$ in $\Sigma$ with $s \subseteq F_{1}^{*} \cup \ldots \cup F_{r}^{*}$, and let $c \in C(\Gamma)$ with $c \cap b d(\Sigma)=s$. Then $c$ is a border cell, and $c \notin \mathcal{A}_{2}$ by definition of $F_{1}^{*} \cup \ldots \cup F_{r}^{*}$. Now $(\alpha(c), B(c)) \in \mathcal{T}$ by (7.1) since it has order $\leq 2 q<\operatorname{ord}(\mathcal{T})$ and $\alpha(c)$ is small with respect to $\mathcal{T}$. By $(3),\left(\alpha(c) \cap G^{\prime}, B(c) \cap G^{\prime}\right) \in \mathcal{T}^{\prime}$ since $(\alpha(c), B(c))$ has order $\leq 2 q<\theta^{\prime}$. Hence $\alpha(c) \cap G^{\prime}$ is small with respect to $\mathcal{T}^{\prime}$. But $\alpha(c) \subseteq G^{\prime}$ since $c \in C(\Gamma) \backslash\left(\mathcal{A}_{1} \cup \mathcal{A}_{2}\right)$, and $\alpha(c)=\mu(s)$. Consequently $\mu(s)$ is small with respect to $\mathcal{T}^{\prime}$. This proves (4).
(5) There is no vital $(p+n)$-linkage in $G^{\prime}$.

Subproof. This follows from (1), (4) and (8.4), because of the choice of $\theta^{\prime}$.

Since $\left(A_{0}, G^{\prime}\right)$ is a separation of $G$ of order $\leq n$, it follows from (5) and (2.4) that there is no vital $p$-linkage in $G$, as required.

## 10 The main proof

Finally we are able to apply the theorems of [10]. Theorems (8.2), (8.4), (9.8) and particularly (13.4) of [10] imply the following. (A $K_{n}$-minor of $G$ is a minor isomorphic to $K_{n}$.)
10.1 For every integer $n \geq 0$ there exist $\rho, \xi \geq 0, q \geq 1$ and $\theta>\xi$ such that, if a graph $G$ has no $K_{n}$-minor, and $\mathcal{T}$ is a tangle in $G$ of order $\geq \theta$, then there exists a surface $\Sigma$ such that $c(\Sigma) \leq \rho$ and $K_{n}$ cannot be drawn in $\Sigma$, and there exists $Z \subseteq V(G)$ with $|Z| \leq \xi$ such that there is a portrait of $G \backslash Z$ in $\Sigma$ with depth $\leq q$, surrounding $\mathcal{T} \backslash Z$.

We deduce
10.2 For all integers $n, p \geq 0$ there exists $\theta \geq 1$ such that, if a graph $G$ has a tangle of order $\geq \theta$ and has no $K_{n}$-minor then $G$ has no vital p-linkage.

Proof. Choose $\rho, \xi \geq 0, q \geq 1$ and $\theta_{1}>\xi$ so that (10.1) holds with $\theta$ replaced by $\theta_{1}$. Choose $\theta_{2} \geq 1$ so that for all surfaces $\Sigma$ with $c(\Sigma) \leq \rho$ in which $K_{n}$ cannot be drawn, (9.2) holds, with $\Sigma, p, q, \theta$ replaced by $\Sigma, p+2 \zeta, q, \theta_{2}$. Let $\theta=\max \left(\theta_{1}, \xi+\theta_{2}\right)$. We claim that $\theta$ satisfies (10.2). For let $G$ have a tangle $\mathcal{T}$ of order $\geq \theta$, and have no $K_{n}$-minor. By (10.1), since $\theta \geq \theta_{1}$, there is a surface $\Sigma$ with $c(\Sigma) \leq \rho$ in which $K_{n}$ cannot be drawn, and there exists $Z \subseteq V(G)$ with $|Z| \leq \xi$ such that there is a portrait of $G \backslash Z$ in $\Sigma$ with depth $\leq q$, surrounding $\mathcal{T} \backslash Z$. Since $\mathcal{T} \backslash Z$ has order $\geq \theta-|Z| \geq \theta_{2}$, it follows from (9.2) that $G \backslash Z$ has no vital $(p+2 \xi)$-linkage. Hence by (2.1), $G$ has no vital $p$-linkage, as required.
10.3 For every integer $p \geq 0$, no graph with a $K_{n}$-minor has a vital p-linkage, where $n=\left\lfloor\frac{5}{2} p\right\rfloor+1$.

Proof. Suppose that $L$ is a vital $p$-linkage in a graph $G$ with a $K_{n}$-minor. Let $Z$ be the set of terminals of $L$. By theorem (6.1) of [8], there exists $v \in V(G) \backslash Z$ such that, in the language of [8], $G$ and $G \backslash v$ have the same 0 -folio relative to $Z$. In particular, there is a linkage in $G \backslash v$ with the same pattern as $L$, a contradiction since $L$ is vital. The result follows.

From (10.2) and (10.3) we deduce the following, which in view of (3.1) implies our main result (1.1).
10.4 For every integer $p \geq 0$ there exists $\theta \geq 1$ such that, if a graph $G$ has a tangle of order $\geq \theta$ then $G$ has no vital p-linkage.

Proof. Let $n$ be as in (10.3), and choose $\theta$ so that (10.2) is satisfied. Let $G$ be a graph with a tangle of order $\geq \theta$. If $G$ has no $K_{n}$-minor then by (10.2) $G$ has no vital $p$-linkage. If $G$ has a $K_{n}$-minor then by (10.3) $G$ has no vital $p$-linkage. The result follows.

## 11 Intertwinings

The "intertwining conjecture", of Lovász [2] and of Milgram and Ungar [3], states that for every two graphs $G_{1}$ and $G_{2}$, there is a finite list $H_{1}, \ldots, H_{n}$ of graphs, such that a graph $G$ topologically
contains both $G_{1}$ and $G_{2}$ if and only if it topologically contains one of $H_{1}, \ldots, H_{n}$. ( $G$ topologically contains $H$ if some subgraph of $G$ is isomorphic to a subdivision of $H$.) This conjecture was proved in [11] by well-quasi-ordering methods. Our object here is to give a different proof of the intertwining conjecture, one that is "constructive" in the sense that it yields an algorithm which, given $G_{1}$ and $G_{2}$, computes $H_{1}, \ldots, H_{n}$ as above.

Poljak and Turzik [4] showed that the intertwining conjecture is (constructively) implied by another conjecture, (11.1) below, and we shall give a constructive proof of (11.1). Let $L_{1}$ and $L_{2}$ be linkages in a graph $G$. We say that $G$ is an intertwining of $L_{1}$ and $L_{2}$ if $L_{1}^{\prime} \cup L_{2}^{\prime}=G$ for all linkages $L_{1}^{\prime}, L_{2}^{\prime}$ in $G$ such that $L_{i}^{\prime}$ has the same pattern as $L_{i}(i=1,2)$. Let us say a graph $G$ has rank

$$
|E(G)|-|V(G)|+\kappa(G),
$$

where $\kappa(G)$ denotes the number of components of $G$. Poljak and Turzik essentially reduced proving the intertwining conjecture to proving the following.
11.1 For every integer $p \geq 0$ there exists $r(p)$ such that every intertwining of two $p$-linkages has $r a n k \leq r(p)$.

We shall derive (11.1) from (1.1), and the proof will be constructive in the sense that it yields an algorithm to compute a value for $r(p)$ given a numerical value for $p$. Our thanks to A. Gupta and R. Impagliazzo, who proved (11.1) constructively for planar intertwinings (unpublished) and brought the general problem to our attention. Thanks also to R. Thomas, who collaborated with us in discovering a constructive proof of (11.1) (not exactly the one given here).

Let $(T, W)$ be a tree-decomposition of a graph $G$. If $S$ is a subtree of $T$, we define $W(S)=$ $\bigcup(W(t): t \in V(S))$. If $e$ is an edge of $T$, and $T_{1}, T_{2}$ are the two components of $T \backslash e$ and $t_{i}$ is the end of $e$ in $T_{i}(i=1,2)$, then $\left(W\left(T_{1}\right), W\left(T_{2}\right)\right)$ is a separation of $G$ and $W\left(T_{1}\right) \cap W\left(T_{2}\right)=W\left(t_{1}\right) \cap W\left(t_{2}\right)$. We define $W(e)=V\left(W\left(T_{1}\right) \cap W\left(T_{2}\right)\right)$.

We say that a tree-decomposition $(T, W)$ of $G$ is linked if for all $e_{1}, e_{2} \in E(T)$ such that $\left|W\left(e_{1}\right)\right|=$ $\left|W\left(e_{2}\right)\right|=k$ say, and $|W(e)| \geq k$ for all edges $e$ of the path of $T$ between $e_{1}$ and $e_{2}$, there are $k$ mutually vertex-disjoint paths of $G$ between $W\left(e_{1}\right)$ and $W\left(e_{2}\right)$. We need the following lemma.
11.2 Let $G$ be a graph of tree-width $\leq w$. Then there is a linked tree-decomposition $(T, W)$ of $G$, with width $\leq w$, such that every vertex of $T$ has degree $\leq 3$.

Proof. By the main result of [14], there is a linked tree-decomposition $(T, W)$ of $G$, with width $\leq w$. Choose it such that $\Sigma(d(t)-3)$ is minimum, where $d(t)$ is the degree of $t$ in $T$ and the sum is over all $t \in V(T)$ with degree $\geq 3$. Suppose that some $t_{0} \in V(T)$ has degree $\geq 4$. Then we may assume that there is a tree $T^{\prime}$ with an edge $e_{0}$ with ends $t_{1}, t_{2}$, such that $T$ is obtained from $T^{\prime}$ by contracting $e_{0}$, and $t_{0}$ results from identifying $t_{1}$ and $t_{2}$, and such that $t_{1}$ and $t_{2}$ both have degree $\geq 3$. Let $W^{\prime}(t)=W(t)$ if $t \in V\left(T^{\prime}\right) \backslash\left\{t_{1}, t_{2}\right\}$, and let $W^{\prime}\left(t_{1}\right), W^{\prime}\left(t_{2}\right)$ be graphs both with vertex set $W\left(t_{0}\right)$, so that $W^{\prime}\left(t_{1}\right) \cup W^{\prime}\left(t_{2}\right)=W\left(t_{0}\right)$ and $E\left(W^{\prime}\left(t_{1}\right) \cap W^{\prime}\left(t_{2}\right)\right)=\emptyset$. Then $\left(T^{\prime}, W^{\prime}\right)$ is a tree-decomposition of $G$ with width $\leq w$, and $W^{\prime}\left(e_{0}\right)=V\left(W\left(t_{0}\right)\right)$, and if $e \in E\left(T^{\prime}\right) \backslash\left\{e_{0}\right\}$ then $e \in E(T)$ and $W^{\prime}(e)=W(e)$. Let $e_{1}, e_{2} \in E\left(T^{\prime}\right)$ with $\left|W^{\prime}\left(e_{1}\right)\right|=\left|W^{\prime}\left(e_{2}\right)\right|=k$ say, and $\left|W^{\prime}(e)\right| \geq k$ for all edges $e$ of the path of $T^{\prime}$ between $e_{1}$ and $e_{2}$. We claim that there are $k$ mutually vertex-disjoint paths between $W^{\prime}\left(e_{1}\right)$ and $W^{\prime}\left(e_{2}\right)$. If $e_{1}, e_{2} \neq e_{0}$, then $e_{1}, e_{2} \in E(T)$ and the claim therefore holds, since $W^{\prime}\left(e_{2}\right)=W\left(e_{i}\right)(i=1,2)$ and $(T, W)$ is linked. If $e_{1}=e_{2}=e_{0}$ the claim is trivial. If $e_{1}=e_{0}$ and $e_{2} \neq e_{0}$, let $e_{3}$ be the edge of $T$ different from $e_{1}$, between $e_{1}$ and $e_{2}$ with a common end $t_{1}$ say with $e_{1}$. Then $\left|W\left(e_{3}\right)\right| \geq k$, but

$$
W\left(e_{3}\right) \subseteq V\left(W\left(t_{1}\right)\right)=W\left(e_{0}\right)
$$

and $\left|W\left(e_{0}\right)\right|=k$; and so $W\left(e_{0}\right)=W\left(e_{3}\right)$. Since there are $k$ mutually disjoint paths of $G$ between $W\left(e_{3}\right)=W\left(e_{0}\right)$ and $W\left(e_{2}\right)$, the claim follows. Consequently $\left(T^{\prime}, W^{\prime}\right)$ is linked, contrary to the choice of $(T, W)$. We deduce that there is no such $t_{0}$, and so (i) holds, as required.

Secondly, we need the following.
11.3 Let $(T, W)$ be a tree-decomposition of $G$, and let $e_{1}, e_{2} \in E(T)$ be distinct. Let $T_{0}, T_{1}, T_{2}$ be the three components of $T \backslash e_{1}, e_{2}$, where $e_{i}$ has an end in $V\left(T_{0}\right)$ and in $V\left(T_{i}\right)(i=1,2)$. Suppose that $W\left(T_{0}\right) \subseteq W\left(T_{1}\right) \cap W\left(T_{2}\right)$. Let $T^{\prime}$ be the tree obtained from $T_{1} \cup T_{2}$ by adding an edge joining the end of $e_{1}$ in $T_{1}$ to the end of $e_{2}$ in $T_{2}$; and let $W^{\prime}$ be the restriction of $W$ to $V\left(T^{\prime}\right)$. Then $\left(T^{\prime}, W^{\prime}\right)$ is a tree-decomposition of $G$, and if $(T, W)$ is linked then so is $\left(T^{\prime}, W^{\prime}\right)$.

Proof. It is straightforward to check that $\left(T^{\prime}, W^{\prime}\right)$ is a tree-decomposition of $G$. Let $X=V\left(W\left(T_{1}\right) \cap\right.$ $\left.W\left(T_{2}\right)\right)$. Since $W\left(T_{0}\right) \subseteq W\left(T_{1}\right) \cap W\left(T_{2}\right)$ it follows that $W(e)=X$ for every edge $e$ of the path of $T$ between $e_{1}$ and $e_{2}$, and now the second claim follows easily.

Proof of (11.1). Choose $w \geq 0$ so that (1.1) is satisfied. Choose $n \geq 0$ so that (2.7) is satisfied with $k$ replaced by $w+1$, and let $r(p)=2^{n-1} w(w+1)$. We claim that (11.1) holds. For we prove
by induction on $|V(G)|+|E(G)|$ that if $G$ is an intertwining of two $p$-linkages $L_{1}$ and $L_{2}$ then $G$ has $\operatorname{rank} \leq r(p)$.
(1) We may assume that $G$ has no isolated vertices.

Subproof. Suppose that $v \in V(G)$ has degree 0 . For $i=1,2$, let $L_{i}^{\prime}=L_{i}$ if $v \notin V\left(L_{i}\right)$, and $L_{i}^{\prime}=L_{i} \backslash v$ if $v \in V\left(L_{i}\right)$. Then $G \backslash v$ is an intertwining of the $p$-linkages $L_{i}^{\prime}$ and $L_{2}^{\prime}$, and from our inductive hypothesis $G \backslash v$ has rank $\leq r(p)$. But $G$ and $G \backslash v$ have the same rank, and the result follows. This proves (1).
(2) We may assume that $V\left(L_{1}\right)=V\left(L_{2}\right)=V(G)$.

Subproof. Suppose that $v \in V(G) \backslash V\left(L_{2}\right)$ say. By (1) there is an edge $e$ of $G$ incident with $v$, and since $L_{1} \cup L_{2}=G$ it follows that $e \in E\left(L_{1}\right)$. The graph $G / e$ (that is, obtained from $G$ by contracting $e$ ) is an intertwining of $L_{1} / e$ and $L_{2}$, if we regard $L_{2}$ as a subgraph of $G / e$ in the obvious way; and $L_{1} / e$ and $L_{2}$ are both $p$-linkages. From the inductive hypothesis, $G / e$ has rank $\leq r(p)$; but it has the same rank as $G$ (for $e$ is not a loop since $e \in E\left(L_{1}\right)$ ) and so $G$ has rank $\leq r(p)$ ) as required. This proves (2).
(3) We may assume that $L_{1}$ and $L_{2}$ are vital, and $E\left(L_{1} \cap L_{2}\right)=\emptyset$.

Subproof. Suppose that there is a linkage $L_{1}^{\prime}$ in $G$ with the same pattern as $L_{1}$, with $E\left(L_{1}^{\prime} \cap L_{2}\right) \neq \emptyset$. Let $e \in E\left(L_{1}^{\prime} \cap L_{2}\right)$; then $G / e$ is an intertwining of the $p$-linkages $L_{1}^{\prime} / e$ and $L_{2} / e$, and the result follows from the inductive hypothesis. We may therefore assume that there is no such $L_{1}^{\prime}$. Since $L_{1}^{\prime} \cup L_{2}=G$ for every linkage $L_{1}^{\prime}$ with the same pattern as $L_{1}^{\prime}$, it follows that $E\left(L_{1}^{\prime}\right)=E(G) \backslash E\left(L_{2}\right)$, and in particular $E\left(L_{1}\right)=E(G) \backslash E\left(L_{2}\right)$. Since $E\left(L_{1}^{\prime}\right)=E\left(L_{1}\right)$ and hence $L_{1}^{\prime}=L_{1}$ for every linkage $L_{1}^{\prime}$ with the same pattern as $L_{1}$, it follows from (2) that $L_{1}$ is vital, and similarly we may assume that $L_{2}$ is vital. This proves (3).

From (1.1) and (3), $G$ has tree-width $\leq w$. From (11.2) there is a linked tree-decomposition $(T, W)$ of $G$ of width $\leq w$, such that every vertex of $T$ has degree $\leq 3$. From (11.3) we deduce
(4) If $e_{1}, e_{2} \in E(T)$ are distinct, and $T_{0}, T_{1}, T_{2}$ are the three components of $T \backslash e_{1}, e_{2}$ as in (11.3), then $W\left(T_{0}\right) \nsubseteq W\left(T_{1}\right) \cap W\left(T_{2}\right)$.
(5) Every path of $T$ has $<n$ edges.

Subproof. Otherwise there is one with exactly $n$ edges, say $e_{1}, \ldots, e_{n}$ in order. For $1 \leq i \leq n$, let $e_{i}$ have ends $t_{i-1}, t_{i}$, and let the two components of $T \backslash e_{i}$ be $S_{i}, T_{i}$, where $t_{i-1} \in V\left(S_{i}\right)$ and $t_{i} \in V\left(T_{i}\right)$. Let $A_{i}=W\left(S_{i}\right)$ and $B_{i}=W\left(T_{i}\right)$. Since $(T, W)$ is linked, it follows that there are linkages $M_{i i^{\prime}}$ as in (2.7), with $k$ replaced by $w+1$. (Each $\left(A_{i}, B_{i}\right)$ has order $\leq w+1$ since each $\left|V\left(W\left(t_{i}\right)\right)\right| \leq w+1$.) By (2.7), there exist $i, i^{\prime}$ with $1 \leq i<i^{\prime} \leq n$, such that $\left|V\left(A_{i} \cap B_{i}\right)\right|=\left|V\left(A_{i^{\prime}} \cap B_{i^{\prime}}\right)\right|=k$ say, and $\left|V\left(A_{j} \cap B_{j}\right)\right|>k$ for $i<j<i^{\prime}$, and

$$
L_{1} \cap B_{i} \cap A_{i^{\prime}}=L_{2} \cap B_{i} \cap A_{i^{\prime}}=M
$$

say, where $M$ is a linkage with $k$ components, each with one end in $V\left(A_{i} \cap B_{i}\right)$ and the other in $V\left(A_{i^{\prime}} \cap B_{i^{\prime}}\right)$. From (3), $E\left(L_{1} \cap L_{2}\right)=\emptyset$, and so $E(M)=\emptyset$, and consequently $V(M)=V\left(A_{i} \cap B_{i}\right)=$ $V\left(A_{i^{\prime}} \cap B_{i^{\prime}}\right)$. Hence $M \subseteq W\left(S_{i}\right) \cap W\left(T_{i^{\prime}}\right)$. But every vertex and edge of $W\left(T_{i} \cap S_{i^{\prime}}\right)$ belongs to one of $L_{1}, L_{2}$ since $L_{1} \cup L_{2}=G$, and hence belongs to $M$. Consequently,

$$
W\left(T_{i} \cap S_{i^{\prime}}\right)=M \subseteq W\left(S_{i}\right) \cap W\left(T_{i^{\prime}}\right) .
$$

But this contradicts (4). Hence there is no such path, and (5) holds.

From (5) and since $T$ has maximum degree $\leq 3$, it follows that $|V(T)| \leq 2^{n}$. But from (3), $G$ has no parallel edges, for if $e_{1}, e_{2}$ are parallel and $e_{1} \in E\left(L_{1}\right)$ then $L_{1}$ is not vital. Consequently, each $W_{t}$ has $\leq \frac{1}{2} w(w+1)$ edges, since $\left|V\left(W_{t}\right)\right| \leq w+1$. Since $G=W(T)$, it follows that

$$
|E(G)| \leq 2^{n} \cdot \frac{1}{2} w(w+1)=r(p)
$$

and hence the rank of $G$ is also at most $r(p)$, as required.
There is some question of whether this proof is really constructive. Certainly it is, if our proof of (1.1) is constructive; but that proof uses several complicated results from earlier papers in this series, and it is necessary to check back through all these proofs and verify that they are indeed constructive in the sense we require. But they are.

## 12 Path-width

We recall that a path-decomposition of $G$ is a tree-decomposition $(T, W)$ of $G$ such that $T$ is a path, and the path-width of $G$ is the minimum width of all path-decompositions of $G$. We saw in (1.2) that for $p \leq 5$, every graph with a vital $p$-linkage has path-width $\leq p$, and our next objective is to show that (1.1) holds in general with tree-width replaced by path-width. This result is not needed for anything, and is included only as a curiosity.

First, we need the following lemma.
12.1 Let $(A, B),\left(A^{\prime}, B^{\prime}\right)$ be separations of a graph, both of order $k$ and with $A \subseteq A^{\prime}$ and $B^{\prime} \subseteq B$. Suppose that in $B \cap A^{\prime}$ there is a unique set of $k$ mutually vertex-disjoint paths between $V(A \cap B)$ and $V\left(A^{\prime} \cap B^{\prime}\right)$, and every vertex of $B \cap A^{\prime}$ belongs to one of these paths. Then there is a pathdecomposition $(P, W)$ of $G$ where $|V(P)| \geq 2$ with the following properties:
(i) $P$ has ends $s, s^{\prime}$ where $W(s)=A, W(P \backslash s)=B, W\left(P \backslash s^{\prime}\right)=A^{\prime}$ and $W\left(s^{\prime}\right)=B^{\prime}$
(ii) $|W(e)|=k$ for every edge $e$ of $P$
(iii) for each $t \in V(P)$ with $t \neq s, s^{\prime},|E(W(t))|=1$ and if $e, e^{\prime}$ are the two edges of $P$ incident with $t$, then either
(a) $W(e)=W\left(e^{\prime}\right)=V(W(t))$, or
(b) $W(e) \cap W\left(e^{\prime}\right)=X$ say where $|X|=k-1$, and the unique edge of $W(t)$ has ends $v, v^{\prime}$ say, where $W(e)=X \cup\{v\}$ and $W\left(e^{\prime}\right)=X \cup\left\{v^{\prime}\right\}$.

Proof. We proceed by induction on $\left|E\left(B \cap A^{\prime}\right)\right|$. Let $V(A \cap B)=Z$ and $V\left(A^{\prime} \cap B^{\prime}\right)=Z^{\prime}$.
(1) We may assume that no edge of $B \cap A^{\prime}$ has both ends in $Z$.

Subproof. If some edge $e$ of $B \cap A^{\prime}$ has both ends in $Z$, let $A_{1}$ be obtained from $A$ by adding the edge $e$, and let $B_{1}=B \backslash e$. Then $A_{1} \subseteq A^{\prime}$ and $B^{\prime} \subseteq B_{1}$, and in $B \cap A^{\prime}$ there is a unique set of $k$ disjoint paths between $V\left(A_{1} \cap B_{1}\right)$ and $V\left(A^{\prime} \cap B^{\prime}\right)$, so from the inductive hypothesis there is a path-decomposition $\left(P_{1}, W_{1}\right)$ of $B \cap A_{1}$ as in the theorem. Let $P_{1}$ have ends $s_{1}, s_{1}^{\prime}$ where $W_{1}\left(s_{1}\right)=A_{1}$; let $P$ be obtained from $P_{1}$ by adding a new vertex $s$ of degree 1 , adjacent to $s_{1}$; and define $W(s)=A, V\left(W\left(s_{1}\right)\right)=V(A \cap B), E\left(W\left(s_{1}\right)\right)=\{e\}$, and $W(t)=W^{\prime}(t)$ for $t \in V(P) \backslash\left\{s, s_{1}\right\}$.

Then $(P, W)$ satisfies the theorem, as required. Consequently (1) holds.
(2) We may assume that every $v \in Z \backslash Z^{\prime}$ has degree $\neq 1$ in $B \cap A^{\prime}$.

Subproof. If some $v \in Z \backslash Z^{\prime}$ has degree 1 in $B \cap A^{\prime}$, let $e$ be the unique edge of $B \cap A^{\prime}$ incident with $v$, and let $e$ have ends $v, v_{1}$. Let $A_{1}$ be obtained from $A$ by adding $v_{1}$ and $e$, and let $B_{1}=B \backslash v$. Again the result follows from the inductive hypothesis applied to $\left(A_{1}, B_{1}\right)$ and $\left(A^{\prime}, B^{\prime}\right)$. Consequently (2) holds.

Let $P_{1}, \ldots, P_{k}$ be mutually vertex-disjoint paths of $B \cap A^{\prime}$ between $Z$ and $Z^{\prime}$. From the hypothesis,

$$
V\left(B \cap A^{\prime}\right)=V\left(P_{1} \cup \ldots \cup P_{k}\right)
$$

Let $P_{i}$ have ends $z_{i} \in Z$ and $z_{i}^{\prime} \in Z^{\prime}(1 \leq i \leq k)$. Let $z_{i} \neq z_{i}^{\prime}$ for $1 \leq i \leq h$ and $z_{i}=z_{i}^{\prime}$ for $h<i \leq k$, where $0 \leq h \leq k$. Let $H$ be the directed graph with vertex set $\{1, \ldots, h\}$, where there is a directed edge from $i$ to $j$ if some edge $e$ of $B \cap A^{\prime}$ has one end $z_{i}$ and the other end a vertex of $P_{j} \backslash z_{j}$, and $e \notin E\left(P_{i}\right)$.
(3) Every vertex of $H$ has out-degree $\geq 1$.

Subproof. Let $1 \leq i \leq h$; we claim that $i$ has out-degree $\geq 1$ in $H$. Since $i \leq h$ it follows that $z_{i} \neq z_{i}^{\prime}$, and by (2) there is an edge $e$ of $B \cap A^{\prime}$ incident with $z_{i}$ with $e \notin E\left(P_{i}\right)$. Since $V\left(B \cap A^{\prime}\right)=V\left(P_{1}, \ldots, P_{k}\right)$, there exists $j$ with $1 \leq j \leq k$ such that $v \in V\left(P_{j}\right)$, where $e$ has ends $z_{i}, v$. By (1), $v \notin Z$, and in particularly $z_{j} \neq z_{j}^{\prime}$, and hence $j \leq h$. Consequently $i$ is adjacent to $j$ in $H$. This proves (3).
(4) $H$ has no directed circuit.

Subproof. Suppose that $\{1,2, \ldots, r\}$ is the vertex set of a directed circuit of $H$, and there are edges of $H$ from $i$ to $i+1$ for $1 \leq i<r$ and from $r$ to 1 . For $1 \leq i<r$, let $e_{i}$ be an edge of $B \cap A^{\prime}$ with one end $z_{i}$ and the other end in $P_{i+1} \backslash z_{i+1}$, and let $e_{r} \in E\left(B \cap A^{\prime}\right)$ with one end $z_{r}$ and the other end in $P_{1} \backslash z_{1}$. For $1 \leq i<r$, let $P_{i}^{\prime}$ be the path consisting of $z_{i}, e_{i}$ and the subpath of $P_{i+1}$ from the end of $e_{i}$ to $z_{i+1}^{\prime}$, and define $P_{r}^{\prime}$ similarly. Then $\left\{P_{1}^{\prime}, \ldots, P_{r}^{\prime}, P_{r+1}, \ldots, P_{k}\right\}$ is a set of $k$ mutually
disjoint paths of $G$ between $Z$ and $Z^{\prime}$, different from $\left\{P_{1}, \ldots, P_{p}\right\}$, since $e_{1}$ is an edge of one of them. This contradicts our hypothesis, and hence (4) follows.

From (3) and (4) it follows that $V(H)=\emptyset$, and so $z_{i}=z_{i}^{\prime}$ for $1 \leq i \leq k$. Hence

$$
V\left(B \cap A^{\prime}\right)=V\left(P_{1} \cup \ldots \cup P_{k}\right)=Z
$$

and so $E\left(B \cap A^{\prime}\right)=\emptyset$, from (1). The theorem is therefore satisfied by a 2 -vertex path $P$.
The converse of (12.1) is obvious, that if there is a path-decomposition satisfying (i), (ii) and (iii), then there is a unique set of $k$ paths as in the hypothesis.

Secondly we need the following.
12.2 Let $(T, W)$ be a linked tree-decomposition of a graph $G$, with width $\leq w$. Let $f_{1}, f_{2} \in E(T)$ be distinct, and let $T_{1}, T_{2}, T_{0}$ be the three components of $T \backslash\left\{f_{1}, f_{2}\right\}$ where $f_{i}$ has ends in $T_{i}$ and $T_{0}(i=$ 1,2). Let $\left|W\left(f_{1}\right)\right|=\left|W\left(f_{2}\right)\right|=k$, and let $\left(P, W^{\prime}\right)$ be a path-decomposition of $G$ satisfying statements (i)-(iii) of (12.1), with $W, A, B, A^{\prime}, B^{\prime}$ replaced by $W^{\prime}, W\left(T_{1}\right), W\left(T_{0}\right) \cup W\left(T_{2}\right), W\left(T_{0}\right) \cup W\left(T_{1}\right), W\left(T_{2}\right)$. Let $P$ have ends $s_{1}, s_{2}$, where $s_{i}$ is the end of $f_{i}$ in $V\left(T_{i}\right)(i=1,2)$, and otherwise let $P$ be disjoint from $T$. Let $T^{*}$ be the tree $T_{1} \cup T_{2} \cup P$, and define $W^{*}(t)=W(t)$ if $t \in V\left(T_{1}\right) \cup V\left(T_{2}\right)$ and $W^{*}(t)=W^{\prime}(t)$ if $t \in V(P) \backslash\left\{s, s^{\prime}\right\}$. Then $\left(T^{*}, W^{*}\right)$ is a linked tree-decomposition of $G$, with width $\leq w$.

Proof. It is easy to see that $\left(T^{*}, W^{*}\right)$ is a tree-decomposition of $G$. We shall check its width, and check that it is linked. Since $\left(P, W^{\prime}\right)$ satisfies (12.1)(iii), it follows that
(1) There are $k$ mutually vertex-disjoint paths of $G$ between $W\left(f_{1}\right)$ and $W\left(f_{2}\right)$. Let $Q$ be the path of $T$ with first and last edges $f_{1}$ and $f_{2}$. From (1), we have
(2) $|W(e)| \geq k$ for each edge $e$ of $Q$.
(3) $\left(T^{*}, W^{*}\right)$ has width $\leq w$.

Subproof. If $t \in V\left(T_{1}\right) \cup V\left(T_{2}\right)$ then $\left|V\left(W^{*}(t)\right)\right|=|V(W(t))| \leq w+1$, and if $t \in V(P) \backslash\left\{s_{1}, s_{2}\right\}$, then

$$
\left.\mid V\left(W^{*}\right)\right)\left|=\left|V\left(W^{\prime}(t)\right)\right| \leq k+1=\left|W\left(f_{1}\right)\right|+1 \leq w+2 .\right.
$$

If $k \leq w$ then (3) holds, and so we assume that $k=w+1$. From (2), $|W(e)| \geq w+1$ for each $e \in E(Q)$, and so $V\left(W\left(t_{1}\right)\right)=V\left(W\left(t_{2}\right)\right)$ if $e \in E(Q)$ has ends $t_{1}, t_{2}$, since

$$
W(e) \subseteq V\left(W\left(t_{1}\right)\right) \cap V\left(W\left(t_{2}\right)\right)
$$

and $\left|V\left(W\left(t_{1}\right)\right)\right|,\left|V\left(W\left(t_{2}\right)\right)\right| \leq w+1$. Consequently, $V(W(t))=W\left(f_{1}\right)$ for all $t \in V(Q)$, and in particular $W\left(f_{1}\right)=W\left(f_{2}\right)$. Hence $W^{\prime}(f)=W\left(f_{1}\right)$ for all $f \in E(P)$, and so $\left|V\left(W^{*}(t)\right)\right| \leq k=w+1$ for each $t \in V(P) \backslash\left\{s_{1}, s_{2}\right\}$, by (12.1)(ii). This proves (3).

Let $e_{1}, e_{2} \in E\left(T^{*}\right)$ with $\left|W^{*}\left(e_{1}\right)\right|=\left|W^{*}\left(e_{2}\right)\right|=k^{\prime}$ say, such that $\left|W^{*}(e)\right| \geq k^{\prime}$ for all edges $e$ of the path $R$ of $T^{*}$ with first edge $e_{1}$ and last edge $e_{2}$. We must show that there are $k^{\prime}$ mutually vertex-disjoint paths of $G$ between $W^{*}\left(e_{1}\right)$ and $W^{*}\left(e_{2}\right)$. If $e_{1}, e_{2} \in E(P)$ this is clear, and so we may assume that $e_{1} \in E\left(T_{1}\right)$. If $e_{1}, e_{2} \in E\left(T_{1}\right)$ the claim follows since $(T, W)$ is linked, and so we may assume that $e_{2} \in E(P)$ or $e_{2} \in E\left(T_{2}\right)$. If $e_{2} \in E\left(T_{2}\right)$ then $k^{\prime} \leq k$ since $P \subseteq R$, and so $|W(e)| \geq k^{\prime}$ for every edge of $e$ of the path of $T$ between $e_{1}$ and $e_{2}$, by (2); and the claim follows since ( $T, W$ ) is linked. We assume then that $e_{2} \in E(P)$, and so $k^{\prime}=k$. Since $(T, W)$ is linked, there are $k$ mutually disjoint paths of $G$ between $W\left(e_{1}\right)$ and $W\left(f_{1}\right)$, and these are paths of $A=W\left(T_{1}\right)$. Since $\left(P, W^{\prime}\right)$ satisfies (12.1), there are $k$ mutually disjoint paths of $G$ between $W\left(f_{1}\right)$ and $W^{\prime}\left(e_{2}\right)$, and these are paths of $B=W\left(T_{0}\right) \cup W\left(T_{2}\right)$. Since $(A, B)$ is a separation and $V(A \cap B)=W\left(f_{1}\right)$, we can pair these paths to obtain $k$ mutually disjoint paths of $G$ between $W^{*}\left(e_{1}\right)=W\left(e_{1}\right)$ and $W^{*}\left(e_{2}\right)=W^{\prime}\left(e_{2}\right)$, as required. Consequently, $\left(T^{*}, W^{*}\right)$ is linked.

We use these lemmas to prove the main result of this section, the following.
12.3 For every integer $p \geq 0$ there exists $w \geq 0$ such that every graph with a vital p-linkage has path-width $\leq w$.

Proof. Choose $w^{\prime}$ so that (1.1) holds with $w$ replaced by $w^{\prime}$. Choose $n$ so that (2.6) holds with $k$ replaced by $w^{\prime}+1$. Let $w=w^{\prime}+3\left(w^{\prime}+1\right) 2^{n-1}$. We claim that $w$ satisfies (12.3). For let $G$ be a graph with a vital $p$-linkage $L$. By (1.1), $G$ has tree-width $\leq w^{\prime}$. By (11.2), there is a linked tree-decomposition $(T, W)$ of $G$, with width $\leq w^{\prime}$, such that every vertex of $T$ has degree at most 3. Let $N(T)$ be the set of vertices of $T$ with degree 3 in $T$, and let us choose ( $T, W$ ) with $|N(T)|$ minimum.
(1) Let $f_{1}, f_{2} \in E(T)$ with $\left|W\left(f_{1}\right)\right|=\left|W\left(f_{2}\right)\right|=k$ say, and let $T_{0}, T_{1}, T_{2}$ be the three components of
$T \backslash\left\{f_{1}, f_{2}\right\}$ where $f_{i}$ has ends in $T_{0}$ and $T_{i}(i=1,2)$. Suppose that there is a unique set of $k$ mutually vertex-disjoint paths of $W\left(T_{0}\right)$ between $W\left(f_{1}\right)$ and $W\left(f_{2}\right)$ and every vertex of $W\left(T_{0}\right)$ belongs to one of these paths. Then $V\left(T_{0}\right) \cap N(T)=\emptyset$.

Subproof. Let $A=W\left(T_{1}\right), B=W\left(T_{0}\right) \cup W\left(T_{2}\right), A^{\prime}=W\left(T_{0}\right) \cup W\left(T_{1}\right), B^{\prime}=W\left(T_{2}\right)$. Then $B \cap A^{\prime}=W\left(T_{0}\right)$. Choose a path-decomposition $\left(P, W^{\prime}\right)$ as in (12.1) (with $W$ replaced by $W^{\prime}$ ). We may assume that $P$ has ends $s_{1}, s_{2}$, where $s_{i}$ is the end of $f_{i}$ in $T_{i}(i=1,2)$, and otherwise $P$ is disjoint from $T$. Let $\left(T^{*}, W^{*}\right)$ be as in (12.2). Then $N\left(T^{*}\right) \subseteq N(T)$, and so equality holds, from the choice of $(T, W)$; but $V\left(T_{0}\right) \cap N\left(T^{*}\right)=\emptyset$, and so $V\left(T_{0}\right) \cap N(T)=\emptyset$. This proves (1).
(2) $|V(P) \cap N(T)| \leq n$ for every path $P$ of $T$.

Subproof. Suppose not; then there is a path $P$ of $T$ with both ends in $N(T)$ and with $|V(P) \cap N(T)|=$ $n+1$. Let $V(P) \cap N(T)=\left\{t_{0}, t_{1}, \ldots, t_{n}\right\}$, in order on $P$. For $1 \leq i \leq n$, let $f_{i} \in E(P)$, chosen so that $f_{i}$ is between $t_{i-1}$ and $t_{i}$, and of all such edges $\left|W\left(f_{i}\right)\right|$ is minimum; let $S_{i}, T_{i}$ be the two components of $T \backslash e_{i}$ where $t_{0} \in V\left(S_{i}\right)$, and let $A_{i}=W\left(S_{i}\right), B_{i}=W\left(T_{i}\right)$. Then for $1 \leq i<j \leq n, A_{i} \subseteq A_{j}$ and $B_{j} \subseteq B_{i}$. Suppose that $1 \leq i<i^{\prime} \leq n$, and $\left(A_{i}, B_{i}\right)$ and $\left(A_{i^{\prime}}, B_{i^{\prime}}\right)$ have the same order $k$ say, and $\left(A_{j}, B_{j}\right)$ has order $>k$ for $i<j<i^{\prime}$. In other words, $\left|W\left(f_{i}\right)\right|=\left|W\left(f_{i^{\prime}}\right)\right|=k$, and $\left|W\left(f_{j}\right)\right|>k$ for $i<j<i^{\prime}$. From the definition of $f_{j}(1 \leq j \leq n)$, it follows that $|W(e)| \geq k$ for all edges $e$ of the path of $T$ between $f_{i}$ and $f_{i^{\prime}}$. Since $(W, T)$ is linked, there are $k$ mutually vertex-disjoint paths of $G$ between $W\left(f_{i}\right)$ and $W\left(f_{i^{\prime}}\right)$, and so there is a linkage $M_{i i^{\prime}}$ in $B_{i} \cap A_{i^{\prime}}$ with $k$ components, each with one end in $V\left(A_{i} \cap B_{i}\right)$ and the other in $V\left(A_{i^{\prime}} \cap B_{i^{\prime}}\right)$. By (1), since there is a member of $N(T)$ between $e_{i}$ and $e_{i^{\prime}}$, it follows that either $V\left(M_{i i^{\prime}}\right) \neq V\left(B_{i} \cap A_{i^{\prime}}\right)$, or there is more than one choice for $M_{i i^{\prime}}$. In either case, we may choose $M_{i i^{\prime}}$ so that $M_{i i^{\prime}} \neq L \cap B_{i} \cap A_{i^{\prime}}$, since $V\left(L \cap B_{i} \cap A_{i^{\prime}}\right)=V\left(B_{i} \cap A_{i^{\prime}}\right)$. But this contradicts $(2.6)$, since each $\left(A_{j}, B_{j}\right)$ has order $\leq w+1=k$. Hence there is no such path $P$, and so (2) holds.

Since $T$ has maximum degree $\leq 3$, it follows from (2) that $|N(T)| \leq 2^{n}$. Let $Z=\bigcup\left(V\left(W_{t}\right): t \in\right.$ $N(T))$; then $|Z| \leq 2^{n}\left(w^{\prime}+1\right)$. Now every component of $T \backslash N(T)$ is a path, and so we may add edges to $T \backslash N(T)$ to obtain a path $P$. For each $t \in V(P)$, let $W^{\prime}(t)=W(t) \cap(G \backslash Z)$.
(3) $\left(P, W^{\prime}\right)$ is a path-decomposition of $G \backslash Z$.

Subproof. Certainly

$$
\bigcup\left(W^{\prime}(t): t \in V(P)\right)=(G \backslash Z) \cap \bigcup(W(t): t \in V(T \backslash N(T)))=G \backslash Z
$$

and the graphs $W^{\prime}(t)(t \in V(P))$ are mutually edge-disjoint. Let $t, t^{\prime}, t^{\prime \prime} \in V(P)$, with $t^{\prime}$ between $t$ and $t^{\prime \prime}$. We must show that $W^{\prime}(t) \cap W^{\prime}\left(t^{\prime \prime}\right) \subseteq W^{\prime}\left(t^{\prime}\right)$, and may therefore assume that $W^{\prime}(t) \cap W^{\prime}\left(t^{\prime \prime}\right)$ is non-null. If $t$ and $t^{\prime \prime}$ lie in different components of $T \backslash N(T)$, choose $s \in N(T)$ between them; then

$$
W(t) \cap W\left(t^{\prime \prime}\right) \subseteq W(s) \subseteq Z
$$

and so $W^{\prime}(t) \cap W^{\prime}\left(t^{\prime \prime}\right)$ is null, a contradiction. Hence $t$ and $t^{\prime \prime}$ lie in the same component of $T \backslash N(T)$, and $t^{\prime}$ therefore also lies in this component, between $t$ and $t^{\prime \prime}$. Thus $W(t) \cap W\left(t^{\prime \prime}\right) \subseteq W\left(t^{\prime}\right)$, and hence $W^{\prime}(t) \cap W^{\prime}\left(t^{\prime \prime}\right) \subseteq W^{\prime}\left(t^{\prime}\right)$, as required. This proves (3).

Now ( $P, W^{\prime}$ ) has width $\leq w^{\prime}$, and so $G \backslash Z$ has path-width $\leq w^{\prime}$. Since $|Z| \leq 2^{n}\left(w^{\prime}+1\right)$, it follows that $G$ has path-width $\leq w^{\prime}+2^{n}\left(w^{\prime}+1\right)=w$, as required.

Actually, we could repeat the same kind of argument to get even more. Let us say that a graph $G$ is a $p$-chain if there exist $Y, Z \subseteq V(G)$ with $|Y|=|Z| \leq p$, such that there is a unique set of $|X|$ mutually vertex-disjoint paths of $G$ between $Y$ and $Z$, and every vertex of $G$ belongs to one of these paths. (Note that $Y \cap Z$ may be nonempty.) It follows from (12.1) that every $p$-chain has a particularly nice path-decomposition of width $\leq p$, and so the following is a strengthening of (12.3).
12.4 For every integer $p \geq 0$ there exists $p^{\prime} \geq 0$ such that every graph with a vital p-linkage is a $p^{\prime}$-chain.

Proof. We only sketch the proof, since we shall not use the result. Let $w$ be as in (12.3), let $n$ satisfy (2.6) with $k$ replaced by $w+1$, and let $p^{\prime}=(w+1)(2 n+1)$. Let $G$ have a vital $p$-linkage $L$. By (12.3), $G$ has path-width $\leq w$. By a variation of (11.2) (proved in the same way as (11.2), but somewhat easier) there is a linked path-decomposition $(P, W)$ of $G$ with width $\leq w$. Let $t \in V(P)$ have degree 2, and be incident with $e_{1}$ and $e_{2}$ say. We say that $t$ is bad unless $\left|W\left(e_{1}\right)\right|=\left|W\left(e_{2}\right)\right|$ and $t$ satisfies (12.1)(iii). Let us choose $(P, W)$ to minimize the number of bad vertices, and let $B$ be the set of bad vertices. An argument similar to step (2) in the proof of (12.3) implies that $|B| \leq n$. Let $Z=\bigcup(W(t): t \in B)$; then $|Z| \leq(w+1) n$. For each component $C$ of $P \backslash B$, the graph

$$
\bigcup(W(t) \cap(G \backslash Z): t \in V(C))
$$

is a $(w+1)$-chain, since no vertex of $C$ is bad. Hence $G \backslash Z$ is a $(w+1)(n+1)$-chain, since $P \backslash B$ has $\leq n+1$ components, and so $G$ is a $((w+1) n+(w+1)(n+1))$-chain, as required.
