LOCAL FORMULAS FOR THE HYDRODYNAMIC PRESSURE AND APPLICATIONS

PETER CONSTANTIN

Abstract. We provide local formulas for the pressure of incompressible fluids. The pressure can be expressed in terms of its average and averages of squares of velocity increments in arbitrary small neighborhoods. As application, we give a brief proof of the fact that $C^\alpha$ velocities have $C^{2\alpha}$ (or Lipschitz) pressures. We also give some regularity criteria for 3D incompressible Navier-Stokes equations.

Dedicated to the memory of Professor Mark I. Vishik.

1. Introduction

We provide local formulas for the pressure of incompressible fluids. By this we mean expressions that compute a solution of

$$-\Delta p = \sum_{i,j=1}^{3} \frac{\partial^2}{\partial x_i \partial x_j} (u_i u_j),$$

where $u$ is a divergence-free velocity, at $x \in \Omega \subset \mathbb{R}^3$, from the spherical average of the pressure,

$$p(x, r) = \frac{1}{4\pi r^2} \int_{|x-y|=r} p(y) dS(y),$$

and from integrals of increments $(u_i(y) - u_i(x))(u_j(y) - u_j(x))$, for $|y - x| \leq r$, with arbitrary small $r$. No knowledge of the behavior of $u$ outside a small ball is needed. The main ingredient is a kind of monotonicity equation for a modified object

$$b(x, r) = \overline{p}(x, r) + \frac{1}{4\pi r^2} \int_{|x-y|=r} \left( \frac{y-x}{|y-x|} \cdot u(y) \right)^2 dS(y).$$

Date: October 11, 2013.

Key words and phrases. Navier-Stokes equations, Euler equations, pressure, regularity criteria.
This allows us to express the pressure as
\[ p(x) = \beta(x, r) + \pi(x, r) \]
where \( \beta \) is just a local average of the pressure,
\[ \beta(x, r) = \frac{1}{r} \int_r^{2r} \bar{p}(x, \rho) d\rho, \]
and \( \pi(x, r) \) is given by a couple of integrals (39) of squares of increments of velocity over a ball and over an annulus of radii 2r. Thus, we write the pressure as a sum of two local terms, one small, and the other sufficiently well-behaved. Indeed, \( \beta \in L^\infty(\mathbb{R}^3) \) is bounded in space (for any \( r \)), if \( u \in L^2(\mathbb{R}^3) \) (34), and \( \|\nabla \beta\|_{L^2(\mathbb{R}^3)} \) is bounded in terms of \( \|u\|_{L^3(\mathbb{R}^2)}^2 \) (47). On the other hand, \( \pi \) is of the order \( r^2|\nabla u|^2 \) for small \( r \). Well-known criteria for regularity for the 3D incompressible Navier-Stokes equations in terms of the pressure ([1]), ([7]) do exist. If the pressure would obey the bounds that \( \beta \) obeys, then regularity of solutions of the 3D Navier-Stokes equations would easily follow. Because \( \pi(x, r) \to 0 \) as \( r \to 0 \), the suggestion that \( p \) obey the same bounds as \( \beta \) is not unreasonable. On the other hand, bounds on \( \pi \) require some smoothness of the velocity. Higher regularity in space for velocity for weak solutions of the 3D Navier-Stokes equations was obtained in ([4]) (see also ([10])). These bounds imply that \( \pi(x, r) \) is small for almost all time. For instance, \( \|\pi\|_{L^3(\mathbb{R}^3)} \leq C(t)r^2, \ t - a.e. \) (52), (59). The problem is that in general the time integrability of \( C(t) \) is too poor to conclude regularity \( (C(t)^{\frac{1}{3}} \) is time integrable, whereas \( C(t) \) time integrable would be sufficient for regularity.)

The organization of this paper is as follows: In the next section we present the basic calculations which lead to the formulas for the pressure. In section 3 we give ensuing bounds for \( \beta \) and \( \pi \). In section 4 we give a quick proof of the bounds of higher derivatives of solutions of the 3D Navier-Stokes equations in the whole space. These follow from the classical paper ([4]), and were well-known for decades, although, because ([4]) deals with spatially periodic solutions, a proof in the whole space of one the results (due originally to Luc Tartar, see acknowledgment in ([4])) was given only in 2001 ([2]). The 2012 preprint ([9]) contains also a proof of this result and more references. In section 5 we give two applications: the first is a simple proof of the fact that, if \( u \in C^\alpha \), then \( p \in C^{2\alpha} \) (if \( 2\alpha < 1 \); if \( 2\alpha > 1 \) then \( p \) is Lipschitz). This result was used recently in ([5]), with a proof based on the Littlewood-Paley decomposition. A different proof (closer to ours) was obtained before, but was not published ([8]). The 3D Navier-Stokes equations are regular if \( u \in L^\infty([0, T], L^3(\mathbb{R}^3)) \) ([3]), ([6]). We give as a second
application, criteria of regularity for the 3D Navier-Stokes equations in terms of \( \pi \). These essentially say that if we can find \( r(t) \) small such that in some sense, \( \pi \) is small, and if some integral of \( r(t)^{-1} \) is finite, then we have regularity. Some elementary calculations needed for the formulas are presented in the Appendix.

2. Spherical averages

We denote
\[
(1) \quad f(x, r) = \frac{1}{4\pi r^2} \int_{|x-y|=r} f(y) dS(y) = \frac{1}{4\pi} \int_{|\xi|=1} f(x + r\xi) dS(\xi)
\]
where \( f \) denotes normalized integral. We consider solutions of
\[
(2) \quad -\Delta p = \nabla \cdot (u \cdot \nabla u)
\]
in \( \Omega \subset \mathbb{R}^3 \). We assume \( \nabla \cdot u = 0 \) and smoothness of \( u \). We start by computing
\[
\begin{align*}
\partial_i \overline{p}(x, r) &= \int_{|\xi|=1} \xi_i \cdot \nabla x p(x + r\xi) dS(\xi) = \frac{1}{4\pi} \int_{|\xi|=1} \xi_i \cdot \nabla \xi p(x + r\xi) dS(\xi) \\
&= \frac{1}{4\pi} \int_{|\xi|<1} \Delta \xi p(x + r\xi) d\xi = \frac{1}{4\pi} \int_{|\xi|<1} \Delta_x p(x + r\xi) d\xi.
\end{align*}
\]
We use the equation (2). We note that, in view of the incompressibility \( \nabla \cdot u = 0 \), we have
\[
\Delta p = -\partial_i \partial_j ((u_i - v_i)(u_j - v_j))
\]
for any constant vector \( v \). (We use summation convention, unless explicitly stated otherwise.) We have thus
\[
\begin{align*}
\partial_i \overline{p}(x, r) &= -\frac{1}{4\pi} \int_{|\xi|<1} \partial_i \partial_j ((u_i - v_i)(u_j - v_j))(x + r\xi) d\xi \\
&= -\frac{1}{4\pi} \int_{|\xi|<1} \partial_i \partial_j ((u_i - v_i)(u_j - v_j))(x + r\xi) d\xi \\
&= -\frac{1}{4\pi} \int_{|\xi|=1} (\xi_i \partial_j ((u_i - v_i)(u_j - v_j))(x + r\xi) dS(\xi) \\
&= -\frac{1}{4\pi} \int_{|\xi|=1} (\xi_i \partial_j ((u_i - v_i)(u_j - v_j))(x + r\xi) dS(\xi).
\end{align*}
\]
So we have
\[
(3) \quad r \partial_i \overline{p}(x, r) = -\int_{|\xi|=1} \xi_i \partial_j ((u_i - v_i)(u_j - v_j))(x + r\xi) dS(\xi).
\]

Lemma 1. Let \( \Omega \) be an open set in \( \mathbb{R}^3 \), let \( x \in \Omega \). Let \( r < \text{dist}(x, \partial \Omega) \), and let \( u \) be a divergence-free vector field in \( C^2(\Omega)^3 \). Let \( v \in \mathbb{R}^3 \). Let \( p \) solve (2) in \( \Omega \). Then
\[
\begin{align*}
\partial_t \left\{ \overline{p}(x, r) + \int_{|\xi|=1} |\xi \cdot (u(x + r\xi) - v)|^2 dS(\xi) \right\} \\
&= -\frac{1}{r} \int_{|\xi|=1} \left[ 3 |\xi \cdot (u(x + r\xi) - v)|^2 - |u(x + r\xi) - v|^2 \right] dS(\xi).
\end{align*}
\]
Proof. We are going to use the identities
\[ f_{|\xi|=1} \xi_j \partial_{\xi_j} f(x + r\xi) dS(\xi) \]
valid for each \( j \), (no summation of repeated indices in the formula above), and
\[ f_{|\xi|=1} (\xi_i \partial_{\xi_i} + \xi_j \partial_{\xi_j}) f(x + r\xi) dS(\xi) \]
where \( w = u - v \) and the expression is evaluated at \( x + r\xi \). Using (5), (6), we group together the terms involving \( r\partial_r \), and separately the ones which do not involve \( r\partial_r \), and sum. We obtain thus from (3)
\[ r\partial_r \overline{p}(x, r) = -r\partial_r f_{|\xi|=1} (|\xi| \cdot w)^2 dS(\xi) \]
and the expression is evaluated at \( x + r\xi \). Using (5), (6), we group together the terms involving \( r\partial_r \), and separately the ones which do not involve \( r\partial_r \), and sum. We obtain thus from (3)
\[ r\partial_r \overline{p}(x, r) = -r\partial_r f_{|\xi|=1} (|\xi| \cdot w)^2 dS(\xi) \]
which is the same as (4).

Lemma 2. Let \( x \in \Omega \subset \mathbb{R}^3 \), let \( 0 < r < \text{dist}(x, \partial \Omega) \), and let \( p \) solve (2) with divergence-free \( u \in C^2(\Omega)^3 \). Let \( v \in \mathbb{R}^3 \). Then
\[ p(x) + \frac{1}{3} |u(x) - v|^2 = \overline{p}(x, r) + f_{|\xi|=1} |\xi| \cdot (u(x + r\xi) - v)|^2 dS(\xi) \]
and
\[ \lim_{\xi \to 0} f_{|\xi|=1} |\xi| \cdot (u(x + r\xi) - v)|^2 dS(\xi) = \frac{1}{3} \lim_{\xi \to 0} f_{|\xi|=1} |u(x + r\xi) - v|^2 dS(\xi) \]

Proof. This follows immediately from (4) by integration \( \int_0^r d\rho \), noting that
\[ \overline{p}(x, 0) = p(x) \]
and
\[ \lim_{r \to 0} \int_{|\xi|=1} |\xi| \cdot (u(x + r\xi) - v)|^2 dS(\xi) = \frac{1}{3} \lim_{r \to 0} \int_{|\xi|=1} |u(x + r\xi) - v|^2 dS(\xi) \]
The formula (8) can be specialized by choosing \( v \). Before doing this, let us introduce
\[ \sigma_{ij} \overrightarrow{y - x} = 3 \frac{(y_i - x_i)(y_j - x_j)}{|y - x|^2} - \delta_{ij} \]
where
\[ \tilde{y} - \tilde{x} = \frac{y - x}{|y - x|}. \]

Note that
\[ \partial_i \partial_j \left( \frac{1}{|x - y|} \right) = \frac{\sigma_{ij}(\tilde{y} - \tilde{x})}{|y - x|^3}. \]

By choosing \( v = 0 \) in (8) we obtain
\[ p(x) + \frac{1}{3} |u(x)|^2 = \]
\[ \overline{p}(x, r) + \int_{|y - x| = r} |\xi \cdot u(y) - u(y)|^2 dS(y) + \frac{1}{4\pi} \text{PV} \int_{B(x, r)} \frac{\sigma_{ij}(\tilde{x} - \tilde{y})}{|x - y|^3} (u_i u_j)(y) dy. \]

**Remark 1.** If \( \Omega = \mathbb{R}^3 \), if we integrate \( R^{-1} \int_R^2 r dr \) and let \( R \to \infty \) in (12) we obtain (assuming that \( R^{-1} \int_R^2 r dr \) decays)
\[ p(x) + \frac{1}{3} |u(x)|^2 = \frac{1}{4\pi} \text{PV} \int_{\mathbb{R}^3} \frac{\sigma_{ij}(\tilde{x} - \tilde{y})}{|x - y|^3} (u_i u_j)(y) dy \]
a fact that follows also from
\[ p(x) = \frac{1}{4\pi} \int_{\mathbb{R}^3} \frac{1}{|x - y|} \partial_i \partial_j (u_i u_j)(y) dy \]
by integration by parts. So (12) is a local version of this, valid for any \( r > 0 \).

By choosing \( v = u(x) \) in (8), we obtain
\[ p(x) - \overline{p}(x, r) - \int_{|y - x| = r} |\xi \cdot (u(y) - u(x))|^2 dS(y) \]
\[ = \frac{1}{4\pi} \int_{B(x, r)} \frac{\sigma_{ij}(\tilde{x} - \tilde{y})}{|x - y|^3} ((u_i(y) - u_i(x))(u_j(y) - u_j(x))) dy \]
In order to clarify the relationship between (12) and (14) let us observe that
\[ \int_{|y - x| = r} \xi_i (\xi \cdot u(y)) dS(y) + \frac{1}{4\pi} \text{PV} \int_{B(x, r)} \frac{\sigma_{ij}(\tilde{x} - \tilde{y})}{|x - y|^3} u_j(y) dy = \frac{1}{3} u_i(x). \]
This follows from the obvious fact that
\[ \frac{1}{4\pi} \int_{B(x, r)} \frac{y_i - x_i}{|y - x|^3} (\nabla \cdot u)(y) dy = 0 \]
by integration by parts.

**Remark 2.** Letting \( r \to \infty \) we deduce from (15) in the whole space case, if \( u \) decays, that
\[ \frac{1}{4\pi} \text{PV} \int_{\mathbb{R}^3} \frac{\sigma_{ij}(\tilde{x} - \tilde{y})}{|x - y|^3} u_j(y) dy = \frac{1}{3} u_i(x) \]
a fact that follows also from the fact that $\mathbb{P}u = u$ where $\mathbb{P}$ is the projec-
tor on divergence-free functions, using the formula

$$\mathbb{P}v = \frac{2}{3} v + \frac{1}{4\pi} PV \int_{\mathbb{R}^3} \frac{\sigma_{ij}(x-y)}{|x-y|^3} v_j(y) dy.$$  

We write now in the principal value integral in (12)

$$u_i(y)u_j(y) = (u_i(y) - u_i(x))(u_j(y) - u_j(x)) + u_i(x)u_j(y) + u_j(x)u_i(y) - u_i(x)u_j(x)$$

and take advantage of the fact that averages of $\frac{\sigma_{ij}(y-x)}{|y-x|^4}$ on spheres centered at $x$ vanish. Using (15) we obtain

$$p(x) + \frac{1}{3}|u(x)|^2 = \mathcal{P}(x,r) + \int_{|y-x|=r} |\xi \cdot u(y)|^2 dS(y) +$$

$$\frac{1}{4\pi} PV \int_{B(x,r)} \frac{\sigma_{ij}(x-y)}{|x-y|^3}(u_i(y) - u_i(x))(u_j(y) - u_j(x)) dy$$

$$- 2 \int_{|y-x|=r} (\xi \cdot u(x))(\xi \cdot u(y)) dS(y) + \frac{2}{3}|u(x)|^2$$

Rearranging, and noting that

$$\int_{|y-x|=r} (\xi \cdot u(x))^2 dS(y) = \frac{1}{3}|u(x)|^2$$

we obtain

$$p(x) = \mathcal{P}(x,r) + \int_{|y-x|=r} |\xi \cdot (u(y) - u(x))|^2 dS(y) +$$

$$\frac{1}{4\pi} \int_{B(x,r)} \frac{\sigma_{ij}(x-y)}{|x-y|^3}(u_i(y) - u_i(x))(u_j(y) - u_j(x)) dy$$

We have thus:

**Remark 3.** The formula (14) follows directly from (12) by using the formula (15), which is a consequence of the divergence-free condition.

**Remark 4.** The situation in $\mathbb{R}^2$ is entirely similar. Instead of (5) and (6), we have for fixed $j = 1, 2$,

$$\int_{S^1} \xi_j \partial_{\xi_j} f(x + r\xi) dS(\xi)$$

$$= r \partial_r \int_{S^1} \xi_j^2 f(x + r\xi) dS(\xi) + \int_{S^1} (2\xi_j^2 - 1) f(x + r\xi) dS(\xi),$$

and

$$\int_{S^1} (\xi_1 \partial_{\xi_2} + \xi_2 \partial_{\xi_1}) f(x + r\xi) dS(\xi)$$

$$= r \partial_r \int_{S^1} 2\xi_1\xi_2 f(x + r\xi) dS(\xi) + \int_{S^1} 2\xi_1\xi_2 f(x + r\xi) dS(\xi),$$

and consequently, we have instead of (7)

$$r \partial_r \mathcal{P}(x, r) = - r \partial_r \int_{|\xi|=1} (\xi \cdot w)^2 dS(\xi)$$

$$- \int_{|\xi|=1} [2(\xi \cdot w)^2 - |w|^2] dS(\xi),$$

$$\int_{|\xi|=1} [2(\xi \cdot w)^2 - |w|^2] dS(\xi),$$
where \( w = u(x + r\xi) - v \) and \( v \) is a constant vector. This again leads to a local representation formula

\[
(21) \quad p(x) + \frac{1}{2}|u(x) - v|^2 = \bar{p}(x, r) + \int_{\xi=1} |\xi \cdot (u(x + r\xi) - v)|^2 \, dS(\xi)
\]

\[
+ \int_0^r \frac{d\rho}{\rho} \int_{\xi=1} \left[ 2|\xi \cdot (u(x + \rho\xi) - v)|^2 - |u(x + \rho\xi) - v|^2 \right] \, dS(\xi)
\]

We conclude this section by mentioning similar formulae for the average of the gradient of pressure. For instance, starting from the fact that \( \partial_1 p \) solves the equation

\[
(22) \quad - \Delta \partial_1 p = \partial_i \partial_j (\partial_1 (u_i u_j))
\]

obtained by differentiating (2), we arrive at

\[
(23) \quad \partial_r \bar{\partial}_p = - \partial_r \int_{\xi=1} \xi_i \xi_j \left( \partial_{\xi_1} (u_i u_j) (x + r\xi) \right) \, dS(\xi)
\]

\[
- \frac{1}{r} \int_{\xi=1} \left( 3\xi_i \xi_j - \delta_{ij} \right) \left( \partial_{\xi_1} (u_i u_j) (x + r\xi) \right) \, dS(\xi) =
\]

\[
- \partial_r \left( \frac{1}{r} \int_{\xi=1} \xi_i \xi_j \left( \partial_{\xi_1} (u_i u_j) (x + r\xi) \right) \, dS(\xi) \right)
\]

\[
- \frac{1}{r} \int_{\xi=1} \left( 3\xi_i \xi_j - \delta_{ij} \right) \left( \partial_{\xi_1} (u_i u_j) (x + r\xi) \right) \, dS(\xi).
\]

We can integrate by parts in (23), using the relations

\[
(24) \quad \begin{align*}
\int_{\xi=1} \xi_1 \xi_2 \partial_{\xi_1} f(x + r\xi) dS(\xi) &= \rho_1 \rho_2 \, f(x + r\xi) dS(\xi) \\
+ \int_{\xi=1} \xi_1 \xi_3 \partial_{\xi_1} f(x + r\xi) dS(\xi) &= \rho_1 \rho_3 \, f(x + r\xi) dS(\xi) \\
+ \int_{\xi=1} \xi_2 \xi_3 \partial_{\xi_1} f(x + r\xi) dS(\xi) &= \rho_2 \rho_3 \, f(x + r\xi) dS(\xi) \\
\end{align*}
\]

which can be proved in a manner similar to the proofs of (5), (6). After some calculations using the relations above we arrive at

\[
(25) \quad \partial_r \bar{\partial}_p = - \left[ \partial_{\xi_1}^2 + \frac{7}{r^2} \partial_r + \frac{8}{r^2} \right] f_{\xi=1} \xi_1 (\xi \cdot u(x + r\xi))^2 dS(\xi)
\]

\[
+ \frac{2}{r} \left[ \partial_r + \frac{2}{r} \right] f_{\xi=1} u_1 (x + r\xi) (\xi \cdot u(x + r\xi)) dS(\xi)
\]

\[
+ \frac{1}{r} \left[ \partial_r + \frac{2}{r} \right] f_{\xi=1} u_1 (x + r\xi) (\xi \cdot u)^2 \, dS(\xi).
\]

This follows because

\[
(26) \quad \xi_i \xi_j \partial_{\xi_1} u_{i} u_{j} = [r \partial_r + 4] \xi_1 (\xi \cdot u)^2 - 2u_1 (\xi \cdot u)
\]
and
\[
\frac{\partial \xi_i}{\partial x_i} |u(x + r \xi)|^2 = [r \partial_r + 2] \xi_1 |u|^2
\]

3. Representation and bounds

We will take $\Omega = \mathbb{R}^3$ in this section. Let us consider
\[
b(x, r) = \bar{p}(x, r) + \int_{|\xi| = 1} |\xi \cdot u(x + r \xi)|^2 dS(\xi)
\]
The equation (4) with $v = 0$ is
\[
\partial_r b(x, r) = r^{-1} \left[ |u|^2 - 3 |\xi \cdot u(y)|^2 \right](x, r)
\]
and, integrating from $r$ to infinity, and recalling (11) we obtain
\[
b(x, r) = \frac{1}{4\pi} \int_{|x - y| \geq r} \frac{\sigma_{ij}(x - y)}{|x - y|^3} u_i(y) u_j(y) dy
\]

**Proposition 1.** Let $x \in \mathbb{R}^3$, let $r > 0$, let $p$ solve (2) in $\Omega = \mathbb{R}^3$ with divergence-free $u \in (C^2(\mathbb{R}^3) \cap L^2(\mathbb{R}^3))^3$. Let $b$ be defined by (28). Then
\[
\sup_{x \in \mathbb{R}^3} |b(x, r)| \leq \frac{1}{2\pi r^3} \|u\|_{L^2}^2.
\]
If $u \in H^1(\mathbb{R}^2)$, then
\[
\sup_{x \in \mathbb{R}^3} |b(x, r)| \leq \frac{C}{2\pi r} \|
abla u\|_{L^2}^2.
\]
where $C$ is the constant of Hardy’s inequality in $\mathbb{R}^3$.

**Remark 5.** Obviously we do not need $C^2$ regularity for $u$, but rather enough regularity for $b$ to be defined via (28). Of course, the representation (30) requires only $u \in L^2$.

**Remark 6.** The corresponding local result in an open set $\Omega$ is a bound of $b(\cdot, r)$ in $L^\infty(dx)$ in terms of local $L^1(dx)$ bounds for $b$ and $L^2$ (or $H^1$) bounds for $u$. This is obtained in a straightforward manner, by multiplying (29) by an appropriate compactly supported function of $r$ and integrating in $r$.

**Proof.** The proof follows directly from the inequality
\[
|\sigma_{ij}(\xi) u_i u_j| \leq 2|u|^2
\]
valid for any vector $u \in \mathbb{R}^3$ and $\xi \in S^2$, and from Hardy’s inequality
\[
\int_{\mathbb{R}^3} \frac{|u(y)|^2}{|x - y|^2} dy \leq C \int_{\mathbb{R}^3} |\nabla u(y)|^2 dy.
\]
Let us define now

\[ \beta(x, r) = \frac{1}{r} \int_r^{2r} \overline{p}(x, \rho) d\rho \]

**Proposition 2.** Let \( x \in \mathbb{R}^3 \), let \( r > 0 \), let \( p \) solve (2) in \( \Omega = \mathbb{R}^3 \) with divergence-free \( u \in (C^2(\mathbb{R}^3) \cap L^2(\mathbb{R}^3))^3 \). Let \( \beta \) be defined by (33). Then

\[ \sup_{x \in \mathbb{R}^3} |\beta(x, r)| \leq \frac{3}{4\pi r^3} \|u\|_{L^2}^2. \]

If \( u \in H^1(\mathbb{R}^2) \), then

\[ \sup_{x \in \mathbb{R}^3} |\beta(x, r)| \leq \frac{3C}{4\pi r} \|\nabla u\|_{L^2}^2. \]

where \( C \) is the constant of Hardy’s inequality in \( \mathbb{R}^3 \).

**Proof.** We note that

\[ \beta(x, r) = \frac{1}{r} \int_r^{2r} (b(x, \rho) - (\xi \cdot u)(x, \rho)) d\rho \]

The inequalities follow in straightforward manner from

\[ \frac{1}{r} \int_r^{2r} (\xi \cdot u)^2(x, \rho) d\rho = \frac{1}{4\pi r} \int_{r \leq |x-y| \leq 2r} \left( \frac{x-y}{|x-y|} \cdot u(y) \right)^2 \frac{dy}{|x-y|^2}, \]

Proposition 1 and Hardy’s inequality.

**Remark 7.** We introduced the average \( \beta(x, r) \) of \( \overline{p}(x, r) \) in order to pass from the pointwise information on \( b(x, r) \) (31), (32), to the pointwise information on \( \beta(x, r) \) (34), (35), without requiring other bounds than \( L^2 \) (or \( H^1 \)) for \( u \).

Let us consider now the weight function

\[ w(\lambda) = \begin{cases} 
1, & \text{if } 0 \leq \lambda \leq 1, \\
2 - \lambda, & \text{if } 1 \leq \lambda \leq 2, \\
0, & \text{if } \lambda \geq 2 
\end{cases} \]

Let us take now the representation formula (14) and average in \( r \). We obtain

**Theorem 1.** Let \( x \in \mathbb{R}^3 \), let \( r > 0 \), let \( p \) solve (2) in \( \Omega = \mathbb{R}^3 \) with divergence-free \( u \in (C^2(\mathbb{R}^3) \cap L^2(\mathbb{R}^3))^3 \). Then

\[ p(x) = \beta(x, r) + \pi(x, r) \]

with \( \beta(x, r) \) given by

\[ \beta(x, r) = \frac{1}{r} \int_r^{2r} \overline{p}(x, \rho) d\rho \]
and $\pi(x, r)$ given by

\begin{equation}
\pi(x, r) = \frac{1}{4\pi} \int_{|y-x| \leq 2r} \frac{1}{|y-x|^2} \left( \frac{y-x}{|y-x|} \cdot (u(y) - u(x)) \right)^2 dy + \frac{1}{4\pi} \int_{|x-y| \leq 2r} w \left( \frac{|y-x|}{r} \right) \sigma_{ij}(x-y) (u_i(y) - u_i(x))(u_j(y) - u_j(x)) dy
\end{equation}

Remark 8. Passing to the limit $r \to \infty$ in (37) we obtain

\begin{equation}
p(x) = \frac{|u(x)|^2}{3} + \frac{1}{4\pi} \int_{\mathbb{R}^3} \sigma_{ij}(z) (u_i(x+z) - u_i(x))(u_j(x+z) - u_j(x)) dz
\end{equation}

This can be obtained also from (13) using (16).

**Proof.** We integrate $\frac{1}{r} \int_r^{2r} dp$ the representation (14) written as

\begin{equation}
p(x) = \overline{p}(x, \rho) + \int_{|y-x|=\rho} |\xi \cdot (u(y) - u(x))|^2 dS(y) + \int_0^\rho \int_{|y-x|=\lambda} [3(|\xi \cdot (u(y) - u(x))|^2 - |u(y) - u(x)|^2)] dS(y)
\end{equation}

and use the fact that

\[
\frac{1}{r} \int_r^{2r} \left( \int_0^\rho f(l) dl \right) d\rho = \int_0^{2r} w \left( \frac{l}{r} \right) f(l) dl.
\]

In addition to the bounds (34) and (35) we also have bounds that follow from Morrey inequality

\[
\int_{\mathbb{R}^3} |u(y)|^6 dy \leq C \left[ \int_{\mathbb{R}^3} |\nabla u(y)|^2 dy \right]^3,
\]

the representation

\begin{equation}
p = R_i R_j (u_i u_j)
\end{equation}

of the pressure where $R_i = \partial_i (-\Delta)^{-\frac{1}{2}}$ are Riesz transforms, and the boundedness of Riesz transforms in $L^p$ spaces.

**Proposition 3.** Let $p$ the solution of (2) given by (42). For any $q, 1 < q < \infty$ there exist constants $C_q > 0$, independent of $r > 0$ so that, for any $r > 0$

\begin{equation}
\|\overline{p}(\cdot, r)\|_{L^q(\mathbb{R}^3)} \leq C_q \|u\|^2_{L^2(\mathbb{R}^3)}.
\end{equation}

and

\begin{equation}
\|\beta(\cdot, r)\|_{L^q(\mathbb{R}^3)} \leq C_q \|u\|^2_{L^2(\mathbb{R}^3)}.
\end{equation}

For any $a \in [0, 2)$ there exists $C_a > 0$ such that

\begin{equation}
\|\beta(\cdot, r)\|_{L^3(\mathbb{R}^3)} \leq C_a r^{-a} \|u\|_{L^2(\mathbb{R}^3)}^a \|\nabla u\|^2_{L^2(\mathbb{R}^3)}.
\end{equation}
There exists a constant $C > 0$ so that

\begin{equation}
\|
\nabla \bar{p}(\cdot, r)\|_{L^2} \leq C r^{-1} \|u\|_{L^1(\mathbb{R}^3)}^2
\end{equation}

and

\begin{equation}
\|
\nabla \beta(\cdot, r)\|_{L^2} \leq C r^{-1} \|u\|_{L^1(\mathbb{R}^3)}^2
\end{equation}

**Proof.** The bounds (44) for $\beta$ follow from the bounds (43) for $\bar{p}$ by averaging in $r$. The bounds (43) follow from (42) and the boundedness of Riesz transforms in $L^p$ spaces. The bounds (45) follow from (35), interpolation

\begin{equation}
\|\beta\|_{L^3(\mathbb{R}^3)} \leq \|\beta\|_{L^\infty(\mathbb{R}^3)}^{\frac{2}{3}} \|\beta\|_{L^{3-a}(\mathbb{R}^3)}^{\frac{1}{3}}
\end{equation}

the bound (44) for $q = 3 - a$,

\begin{equation}
\|\beta(\cdot, r)\|_{L^{3-a}(\mathbb{R}^3)} \leq C_a \|u\|_{L^{6-2a}(\mathbb{R}^3)}^2
\end{equation}

and interpolation combined with the Morrey inequality

\begin{equation}
\|u\|_{L^{6-2a}(\mathbb{R}^3)} \leq C \|u\|_{L^2(\mathbb{R}^3)}^{\frac{n}{6-2a}} \|\nabla u\|_{L^2(\mathbb{R}^3)}^{\frac{6-2a}{6}}.
\end{equation}

The bound (47) follows from the bound (46) by averaging in $r$. The bound (46) follows from

\begin{equation}
\|
\nabla \bar{p}(\cdot, r)\|_{L^2(\mathbb{R}^3)} \leq C r^{-1} \|\bar{p}(\cdot, r)\|_{L^2(\mathbb{R}^3)}
\end{equation}

and (43) at $q = 2$. The bound (48) follows from Plancherel and the observation that

\begin{equation}
\hat{\bar{p}}(\xi, r) = \frac{\sin(r|\xi|)}{r|\xi|} \hat{\bar{p}}(\xi).
\end{equation}

Indeed,

\[
\int_{\mathbb{R}^3} e^{-ix \cdot \xi} \bar{p}(x, r) dx = \int_{|\omega| = 1} dS(\omega) \int_{\mathbb{R}^3} e^{-ix \cdot \xi} p(x + r \omega) dx
\]

\[
= \hat{\bar{p}}(\xi) \int_{|\omega| = 1} e^{ir \xi \cdot \omega} dS(\omega)
\]

and the last integral is computed conveniently choosing coordinates so that $\xi$ points to the North pole:

\[
\frac{1}{4\pi} \int_0^{2\pi} d\phi \int_0^\pi r e^{i r |\xi| \cos \theta} \sin \theta d\theta = \frac{\sin(r|\xi|)}{r|\xi|}.
\]

Regarding $\pi$ we have

**Proposition 4.** Let $\pi(x, r)$ be defined by (39). Then

\begin{equation}
|\pi(x, r)| \leq C \int_{|z| \leq 2r} \frac{|u(x + z) - u(x)|^2}{|z|^3} dz.
\end{equation}

Consequently

\begin{equation}
\|\pi(\cdot, r)\|_{L^q} \leq C_q r^2 \|
\nabla u\|_{L^2}^2
\end{equation}
holds for all $1 < q \leq \infty$. In particular, at $q = 3$ we have, with Morrey’s inequality,

\begin{equation}
\|\pi(\cdot, r)\|_{L^3} \leq C r^2 \|\Delta u\|_{L^2}^2.
\end{equation}

We also have

\begin{equation}
\|\pi(\cdot, r)\|_{L^q(\mathbb{R}^3)} \leq C_q \|u\|_{L^2q(\mathbb{R}^3)}^2.
\end{equation}

**Proof.** The inequality (50) is immediate from definition. In order to prove (51) we write

\[ |u(x + z) - u(x)|^2 \leq |z|^2 \int_0^1 |\nabla u(x + \lambda z)|^2 d\lambda \]

and changing order of integration we have

\[ \left| \int_{\mathbb{R}^3} \phi(x)dx \int_{|z| \leq 2r} \frac{|u(x + z) - u(x)|^2}{|z|^3} dz \right| \leq C r^2 \|\phi\|_{L^q} \|\nabla u\|_{L^2q}^2 \]

which proves (51). The bounds (53) follow from (37), the corresponding bounds for $p$, and (44).

4. FGT bounds in the whole space

We take the Navier-Stokes equation

\begin{equation}
\partial_t u + u \cdot \nabla u - \nu \Delta u + \nabla p = 0,
\end{equation}

with

\begin{equation}
\nabla \cdot u = 0,
\end{equation}

multiply by $\partial_t u - \nu \Delta u$ and integrate, using incompressibility:

\[ \int_{\mathbb{R}^3} |\partial_t u - \nu \Delta u|^2 dx = - \int_{\mathbb{R}^3} (u \cdot \nabla u)(\partial_t u - \nu \Delta u)dx. \]

Schwartz inequality gives:

\[ \int_{\mathbb{R}^3} |\partial_t u - \nu \Delta u|^2 dx \leq \int_{\mathbb{R}^3} |u \cdot \nabla u|^2 dx \]

and so

\[ \int_{\mathbb{R}^3} |\partial_t u - \nu \Delta u|^2 dx \leq \|u\|_{L^\infty}^2 \|\nabla u\|_{L^2}^2. \]

The inequality

\begin{equation}
\|u\|_{L^\infty}^2 \leq C \|\nabla u\|_{L^2} \|\Delta u\|_{L^2}
\end{equation}

is easy to prove using Fourier transform. Thus

\[ \int_{\mathbb{R}^3} |\partial_t u - \nu \Delta u|^2 dx \leq C \|\Delta u\|_{L^2} \|\nabla u\|_{L^2}^3. \]
On the other hand,
\[ \int_{\mathbb{R}^3} |\partial_t u - \nu \Delta u|^2 \, dx = \|\partial_t u\|_{L^2}^2 + \nu^2 \|\Delta u\|_{L^2}^2 + \nu \frac{d}{dt} \|\nabla u\|_{L^2}^2 \]
and therefore
\[ \frac{d}{dt} \|\nabla u\|_{L^2}^2 + \nu \|\Delta u\|_{L^2}^2 + \frac{1}{2} \|\partial_t u\|_{L^2}^2 \leq \frac{C}{\nu} \|\Delta u\|_{L^2}^2 \|\nabla u\|_{L^2}^2 \leq \frac{\nu}{2} \|\Delta u\|_{L^2}^2 + \frac{C}{\nu^2} \|\nabla u\|_{L^2}^6 \]
Now we denote \( y(t) = \|\nabla u(\cdot, t)\|_{L^2}^2 \), pick a constant \( A > 0 \), divide by \((A + y)^2\) and obtain
\[ -\frac{d}{dt} \left( \frac{1}{A + y} \right) + \nu \frac{\|\Delta u\|_{L^2}^2}{(A + y)^2} + \frac{\|\partial_t u\|_{L^2}^2}{\nu(A + y)^2} \leq \frac{C}{\nu^3} y. \]
Integrating in time we obtain
\[ \int_0^T \nu \|\Delta u\|_{L^2}^2 \, dt + \int_0^T \frac{\|\partial_t u\|_{L^2}^2}{\nu(A + y)^2} \, dt \leq \frac{C}{\nu^4} \|u_0\|_{L^2}^2 + \frac{1}{A} \]
Therefore
\[ (57) \quad \int_0^T \frac{\|\Delta u\|_{L^2}^2}{(A + y)^2} \, dt \leq \frac{C}{\nu^5} \|u_0\|_{L^2}^2 + \frac{1}{\nu A} = C \nu^{-4}[D + \nu^3 A^{-1}] \]
and
\[ (58) \quad \int_0^T \frac{\|\partial_t u\|_{L^2}^2}{(A + y)^2} \, dt \leq \frac{C}{\nu^3} \|u_0\|_{L^2}^2 + \frac{\nu}{A} = C \nu^{-2}[D + \nu^{-3} A^{-1}] \]
where we put
\[ D = \frac{\|u_0\|_{L^2}^2}{\nu}. \]
Now
\[ \int_0^T \|\Delta u\|_{L^2}^2 \, dt \leq \left[ \int_0^T \frac{\|\Delta u\|_{L^2}^2}{(A + y)^2} \, dt \right]^\frac{1}{2} \left[ \int_0^T (A + y) \, dt \right]^\frac{1}{2} \]
and
\[ \int_0^T \|\partial_t u\|_{L^2}^2 \, dt \leq \left[ \int_0^T \frac{\|\partial_t u\|_{L^2}^2}{(A + y)^2} \, dt \right]^\frac{1}{2} \left[ \int_0^T (A + y) \, dt \right]^\frac{1}{2} \]
and therefore
\[ \int_0^T \|\Delta u\|_{L^2}^2 \, dt \leq C \nu^{-\frac{3}{2}} [D + \nu^3 A^{-1}]^\frac{1}{2} [D + AT]^\frac{3}{2} \]
and
\[ \int_0^T \|\partial_t u\|_{L^2}^2 \, dt \leq C \nu^{-\frac{3}{2}} [D + \nu^3 A^{-1}]^\frac{1}{2} [D + AT]^\frac{3}{2} \]
Now \( A \) is arbitrary, but a natural explicit choice is
\[ A^2 = \nu^3 T^{-1} \]
and then we have
\begin{equation}
(59) \quad \int_0^T \|\Delta u\|_{L^2}^2 dt \leq C\nu^{-\frac{3}{4}} \left[ \frac{\|u_0\|_{L^2}^2}{\nu} + T^{\frac{1}{2}}\nu^{\frac{3}{2}} \right]
\end{equation}
and
\begin{equation}
(60) \quad \int_0^T \|\partial_t u\|_{L^2}^2 dt \leq C\nu^{-\frac{3}{4}} \left[ \frac{\|u_0\|_{L^2}^2}{\nu} + T^{\frac{1}{2}}\nu^{\frac{3}{2}} \right].
\end{equation}
Now using the inequality (56) it follows immediately that
\begin{equation}
(61) \quad \int_0^T \|u\|_{L^\infty} dt \leq C\nu^{-1} \left[ \frac{\|u_0\|_{L^2}^2}{\nu} + T^{\frac{3}{2}}\nu^{\frac{3}{2}} \right]^{\frac{1}{4}} \left[ \frac{\|u_0\|_{L^2}^2}{\nu} \right]^{\frac{1}{4}}.
\end{equation}
Let us consider now the other terms in (54). We start by computing
\begin{equation}
\int_{\mathbb{R}^3} |u \cdot \nabla u + \nabla p|^2 \, dx = \|u \cdot \nabla u\|_{L^2}^2 + \|\nabla p\|_{L^2}^2 + 2 \int_{\mathbb{R}^3} (u \cdot \nabla u) \cdot (\nabla p) \, dx.
\end{equation}
Now
\begin{equation}
2 \int_{\mathbb{R}^3} (u \cdot \nabla u) \cdot (\nabla p) \, dx = -2 \int \text{Tr}(\nabla u)^2 \, dx = 2 \int_{\mathbb{R}^3} p \Delta p \, dx = -2\|\nabla p\|_{L^2}^2.
\end{equation}
Consequently
\begin{equation}
0 \leq \int_{\mathbb{R}^3} |u \cdot \nabla u + \nabla p|^2 \, dx = \|u \cdot \nabla u\|_{L^2}^2 - \|\nabla p\|_{L^2}^2.
\end{equation}
On the other hand, obviously
\begin{equation}
\|u \cdot \nabla u\|_{L^2} \leq \|u\|_{L^\infty} \|\nabla u\|_{L^2}
\end{equation}
and in view of the previous result we have
\begin{equation}
(62) \quad \int_0^T \|u \cdot \nabla u\|_{L^2}^2 dt \leq C\nu^{-\frac{3}{4}} \left[ \frac{\|u_0\|_{L^2}^2}{\nu} + T^{\frac{1}{2}}\nu^{\frac{3}{2}} \right]^{\frac{1}{2}} \left[ \frac{\|u_0\|_{L^2}^2}{\nu} \right]^{\frac{1}{2}}
\end{equation}
and, because of the inequality \( \|\nabla p\|_{L^2} \leq \|u \cdot \nabla u\|_{L^2} \), we also have
\begin{equation}
(63) \quad \int_0^T \|\nabla p\|_{L^2}^2 dt \leq C\nu^{-\frac{3}{4}} \left[ \frac{\|u_0\|_{L^2}^2}{\nu} + T^{\frac{1}{2}}\nu^{\frac{3}{2}} \right]^{\frac{1}{2}} \left[ \frac{\|u_0\|_{L^2}^2}{\nu} \right]^{\frac{1}{2}}
\end{equation}
We have thus

**Theorem 2.** Let \( u \) be a Leray weak solution of the Navier-Stokes equation on the interval \([0, T]\). Then the quantities \( \|u\|_{L^\infty(\mathbb{R}^3)}, \|\Delta u\|_{L^2(\mathbb{R}^3)}^2, \|\partial_t u\|_{L^2(\mathbb{R}^3)}^2, \|u \cdot \nabla u\|_{L^2(\mathbb{R}^3)}^2, \|\nabla p\|_{L^2(\mathbb{R}^3)}^2 \) are almost everywhere finite on the time interval \([0, T]\), and their time integrals are bounded uniformly, with bounds (59, 60, 61, 62, 63) depending only on \( T, \|u_0\|_{L^2(\mathbb{R}^3)} \) and \( \nu \).
The proof for Leray weak solutions follows the same pattern as the proof given above for smooth solutions, except that we mollify the advecting velocity, prove the mollification-uniform bounds and deduce the result using essentially Fatou’s lemma. For the sake of completeness, let us mention here other estimates. Interpolating

$$\int_0^T \|\nabla u\|_{L^2}^2 dt < \infty$$

and

$$\int_0^T \|\nabla u\|_{L^6}^3 dt < \infty$$

which comes from Morrey’s inequality and (59) we get

$$\|\nabla u\|_{L^3} \leq C\|\nabla u\|_{L^2}^{\frac{1}{2}}\|\nabla u\|_{L^6}^{\frac{3}{2}}$$

which then is integrable by Hölder

$$\int_0^T \|\nabla u\|_{L^3} dt < \infty.$$ 

Finally, we mention that, interpolating between $L^\infty(dt; L^2(dx))$ and $L^2(dt; L^6(dx))$ it is easy to see that $u \in L^p(dt, L^q(dx))$ for $q = \frac{6p}{3p-4}$ if $p \geq 2$. For $p \in [1, 2]$ interpolating between $L^2(dt; L^6(dx))$ and $L^1(dt, L^\infty(dx))$ we get $q = \frac{3p}{p-1}$.

5. Applications

**Theorem 3.** Let $u$ solve (54) and (55) in $\mathbb{R}^3$ and assume that $u$ belongs to $L^\infty(dt; L^2(\mathbb{R}^3)) \cap L^2(dt; C^\alpha(\mathbb{R}^3))$ for some $q \geq 1$. Then $p \in L^q(dt; C^{2\alpha}(\mathbb{R}^3))$ if $\alpha < \frac{1}{2}$. If $\alpha = \frac{1}{2}$ then $p \in L^q(dt; \text{LiplogLip})$ where LiplogLip is the class of functions with modulus of continuity $|x-y|\log(|x-y|^{-1})$. If $\alpha > \frac{1}{2}$ then $p \in L^q(dt; \text{Lip})$ where Lip is the class of Lipschitz continuous functions.

**Proof.** We start with two points $x, y$ at distance $|x-y|$ and we choose $r = 8|x-y|$. The representation (14) implies

$$|p(x) - p(x, r)| \leq C\|u\|_{C^{\alpha}}^2 r^{2\alpha},$$

$$|p(y) - p(y, r)| \leq C\|u\|_{C^{\alpha}}^2 r^{2\alpha},$$

so, it remains to prove that

$$|\overline{p}(x, r) - \overline{p}(y, r)| \leq C r^{2\alpha}$$

if $2\alpha < 1$ and $C \sim \|u\|_{C^{\alpha}}^2$. (If $2\alpha = 1$ we obtain $r \log(r^{-1})$, and if $2\alpha > 1$, $r$.) In order to do so, we use (4) with $v = u\left(\frac{x+y}{2}\right)$ and
integrate from $r$ to infinity. We obtain

$$
\overline{p}(x, r) = -\int_{|\xi|=1} (\xi \cdot (u(x + r\xi) - v)^2 dS(\xi) + \frac{1}{4\pi} \int_{|x-z|\geq r} \frac{\sigma_{ij}(x-z)}{|x-z|^3} (u_i(z) - v_i)(u_j(z) - v_j) dz
$$

and

$$
\overline{p}(y, r) = -\int_{|\xi|=1} (\xi \cdot (u(y + r\xi) - v)^2 dS(\xi) + \frac{1}{4\pi} \int_{|y-z|\geq r} \frac{\sigma_{ij}(y-z)}{|y-z|^3} (u_i(z) - v_i)(u_j(z) - v_j) dz
$$

Now clearly

$$
\left| \int_{|\xi|=1} (\xi \cdot (u(x + r\xi) - v)^2 dS(\xi) \right| \leq C r^{2\alpha} \|u\|_{C^{2\alpha}}^2,
$$

and

$$
\left| \int_{|\xi|=1} (\xi \cdot (u(y + r\xi) - v)^2 dS(\xi) \right| \leq C r^{2\alpha} \|u\|_{C^{2\alpha}}^2,
$$

so it remains to estimate

$$
\frac{1}{4\pi} \int_{|x-z|\geq r} \frac{\sigma_{ij}(x-z)}{|x-z|^3} w_i w_j dz - \frac{1}{4\pi} \int_{|y-z|\geq r} \frac{\sigma_{ij}(y-z)}{|y-z|^3} w_i w_j dz
$$

where $w = u(y) - v$. Now, if $|x - z| \geq r$ but $|y - z| \leq r$, then $|x - z| \leq |y - z| + |x - y| \leq \frac{9}{8} r$, and so

$$
\left| \frac{1}{4\pi} \int_{|x-z|\geq r, |y-z|\leq r} \frac{\sigma_{ij}(x-z)}{|x-z|^3} w_i w_j dz \right| \leq C \|u\|_{C^{2\alpha}}^2 r^{2\alpha},
$$

and similarly, if $|y - z| \geq r$, but $|x - z| \leq r$, then

$$
\left| \frac{1}{4\pi} \int_{|y-z|\geq r, |x-z|\leq r} \frac{\sigma_{ij}(y-z)}{|y-z|^3} w_i w_j dz \right| \leq C \|u\|_{C^{2\alpha}}^2 r^{2\alpha}.
$$

Finally, we are left with

$$
\frac{1}{4\pi} \int_{|x-z|\geq r, |y-z|\geq r} (K_{ij}(x-z) - K_{ij}(y-z)) w_i w_j dz
$$

where

$$
K_{ij}(\zeta) = (3\zeta_i\zeta_j |\zeta|^{-2} - \delta_{ij}) |\zeta|^{-3}
$$

This is now a classical situation in singular integral theory where the smoothness of the kernel is used. We observe that

$$
|K_{ij}(x - z) - K_{ij}(y - z)| \leq C |x - y| \int_0^1 |z - (y + \lambda(x - y))|^{-4} d\lambda
$$
and that \(|z - (y + \lambda(x - y))| \geq \frac{7}{8} r\). Thus
\[
\left| \frac{1}{4\pi} \int_{|z-x| \geq r, |y-z| \geq r} (K_{ij}(x-z) - K_{ij}(y-z)) w_i w_j dz \right|
\leq C |x-y| \int_0^1 \int_{|z-x| \geq \frac{7}{8} r} |z-x|^{-4} |u(z) - u\left(\frac{x+y}{2}\right)|^2 dz \, d\lambda
\]
where \(x_\lambda = y + \lambda(x - y)\). Now, choosing \(R > 0\) fixed (we could choose \(R = 1\), but we prefer to keep dimensionally correct quantities)
\[
|x-y| \int_0^1 \int_{\frac{7}{8} r \leq |z-x_\lambda| \leq R} |z-x_\lambda|^{-4} |u(z) - u\left(\frac{x+y}{2}\right)|^2 dz \, d\lambda
\leq C |x-y| R^{-1} \|u\|_{L_\infty}^2.
\]
The integral on \(\frac{7}{8} r \leq |z-x_\lambda| \leq R\),
\[
|x-y| \int_0^1 \int_{\frac{7}{8} r \leq |z-x_\lambda| \leq R} |z-x_\lambda|^{-4} |u(z) - u\left(\frac{x+y}{2}\right)|^2 dz \, d\lambda
\]
is estimated using
\[
\left|u(z) - u\left(\frac{x+y}{2}\right)\right| \leq C \|u\|_{C^\alpha}^2 (|z-x_\lambda|^{2\alpha} + r^{2\alpha})
\]
The resulting bound obtained by integrating on \(\frac{7}{8} r \leq |z-x_\lambda| \leq R\) is
\[
C \|u\|_{C^\alpha}^2 |x-y| \left[ \frac{1}{1-2\alpha} r^{2\alpha-1} + r^{2\alpha-1} \right]
\]
if \(2\alpha < 1\),
\[
C \|u\|_{C^\alpha}^2 |x-y| \left[ \log \left(\frac{8R}{r}\right) + 1 - \frac{r}{R} \right]
\]
if \(2\alpha = 1\), and
\[
C \|u\|_{C^\alpha}^2 |x-y| \left[ \frac{R^{2\alpha-1}}{2\alpha - 1} + r^{2\alpha-1} \right]
\]
if \(2\alpha > 1\). This concludes the proof.

We state now some criteria for regularity. We will write \(\pi(x,t,r(t))\) for \(\pi\) defined according to the formula (39) for a time dependent \(u(x,t)\) and with a time dependent \(r = r(t)\). We recall that \(\pi\) is small if \(u\) is regular and \(r\) is small.

**Theorem 4.** Let \(u\) be a smooth solution of the Navier-Stokes equation on the interval \([0,T]\).

First criterion: Assume that there exists \(U > 0\), \(R > 0\) and \(0 < r(t) \leq R\) such that
\[
\int_{\{x \in \mathbb{R}^3 \mid u(x,t) \geq U\}} |u(x,t)||\pi(x,t,r(t))|^2 \, dx \leq \frac{\nu^2}{4} \int_{\mathbb{R}^3} |u(x,t)||\nabla u(x,t)|^2 \, dx
\]
holds. Assume that there exists $\gamma > 4$ such that
\begin{equation}
\int_0^T r(t)^{-\gamma} dt < \infty.
\end{equation}
Then
\begin{equation}
u 
\end{equation}
Second criterion: Assume that there exists $r(t)$ such that $\pi = \pi(x, r(t))$ satisfies
\begin{equation}
\int_0^T \|\pi\|_{L^3(\mathbb{R}^3)}^2 dt < \infty
\end{equation}
and that, as above, there exists $\gamma > 4$ such that (68) holds. Then again (69) holds.

**Proof.** We start with the first criterion. We consider the evolution of the $L^3$ norm of velocity:
\begin{align*}
\frac{d}{dt} \|u\|_{L^3(\mathbb{R}^3)}^3 + \nu \int_{\mathbb{R}^3} |\nabla u|^2 |u| dx + \int_{\mathbb{R}^3} |u| (u \cdot \nabla p) dx &\leq 0
\end{align*}
We represent $p$ using the formula (37) with $r = r(t)$. We split softly the integral involving $\pi$:
\begin{align*}
\int_{\mathbb{R}^3} |u|(u \cdot \nabla \pi) dx &= \int_{\mathbb{R}^3} \phi \left( \frac{|u|}{U} \right) |u|(u \cdot \nabla \pi) dx \\
&\quad + \int_{\mathbb{R}^3} \left( 1 - \phi \left( \frac{|u|}{U} \right) \right) |u|(u \cdot \nabla \pi) dx
\end{align*}
where $\phi(q)$ is a smooth scalar function $0 \leq \phi(q) \leq 1$, supported in $0 \leq q \leq 1$. We use the bound
\begin{align*}
|\nabla \pi(x)| &\leq C \int_0^1 d\lambda \int_{|z| \leq 2r} \frac{dz}{|z|^2} (|\nabla u(x + z)| + |\nabla u(x)| \nabla u(x + \lambda z)|
\end{align*}
which follows from (39) by differentiation. It follows that
\begin{align*}
\left| \int_{\mathbb{R}^3} \phi \left( \frac{|u|}{U} \right) |u|(u \cdot \nabla \pi) dx \right| &\leq C U^2 r \|\nabla u\|_{L^2(\mathbb{R}^3)}^2.
\end{align*}
We integrate by parts in the other piece:
\begin{align*}
\int_{\mathbb{R}^3} \left( 1 - \phi \left( \frac{|u|}{U} \right) \right) |u|(u \cdot \nabla \pi) dx &= -\int_{\mathbb{R}^3} \pi u \cdot \nabla |u| \left( 1 - \phi \left( \frac{|u|}{U} \right) \right) dx
\end{align*}
When the derivative falls on $1 - \phi$ we are in the $|u| \leq U$ regime and we use (53) and the interpolation combined to Morrey’s inequality
\begin{align*}
\|u\|_{L^4(\mathbb{R}^3)}^2 &\leq C \|u\|_{L^3(\mathbb{R}^3)} \|\nabla u\|_{L^2(\mathbb{R}^3)}
\end{align*}
to deduce
\[
\left| \int_{\mathbb{R}^3} \pi |u| u \cdot \nabla |u| U^{-1} \phi' \left( \frac{|u|}{C} \right) \, dx \right| \leq C U \| \pi \|_{L^2(\mathbb{R}^3)} \| \nabla u \|_{L^2(\mathbb{R}^3)}^2
\]
\[
\leq C U \| u \|_{L^3(\mathbb{R}^3)} \| \nabla u \|_{L^2(\mathbb{R}^3)}^2
\]

When the derivative falls on \(|u|\) we use the condition (67) and the Schwartz inequality:
\[
\left| \int_{\{|u(x,t)| \geq U\}} |u \cdot \nabla |u| (1 - \phi \left( \frac{|u|}{C} \right) \pi) \, dx \right| 
\leq \frac{\nu}{2} \int_{\mathbb{R}^3} |u| \| \nabla u \| \, dx.
\]

As to the integral involving \(\beta\), we integrate by parts, and use Hölder’s inequality followed by (45)
\[
\left| \int_{\mathbb{R}^3} \beta u \cdot \nabla |u| \, dx \right| \leq \| \beta \|_{L^3(\mathbb{R}^3)} \| u \|_{L^3(\mathbb{R}^3)} \frac{\nu}{2} \int_{\mathbb{R}^3} |u| \| \nabla u \| \, dx
\]
\[
\leq \frac{1}{\nu} \| \beta \|_{L^3(\mathbb{R}^3)}^2 \| u \|_{L^3(\mathbb{R}^3)} + \frac{\nu}{2} \int_{\mathbb{R}^3} |u| \| \nabla u \| \, dx
\]
\[
\leq C \nu^{-1} r^{-2a} \| u \|_{L^3(\mathbb{R}^3)} \| \nabla u \|_{L^2(\mathbb{R}^3)} \frac{\nu}{2} \int_{\mathbb{R}^3} |u| \| \nabla u \| \, dx
\]

By choosing \(a = \frac{\gamma}{\gamma - 2}\) we have \(a < 2\), and using Young’s inequality, we see that
\[
r^{-2a} \| \nabla u \|_{L^2(\mathbb{R}^3)}^{4 - 2a} \leq C (r^{-\gamma} + \| \nabla u \|_{L^2(\mathbb{R}^3)}^2)
\]
is time-integrable. The upshot is that the quantity \(y(t) = \| u \|_{L^3(\mathbb{R}^3)}\) obeys an ordinary differential inequality
\[
y^2 \frac{dy}{dt} \leq C_1(t) + C_2(t) y + C_3(t) y
\]
with \(C_1(t) = CU^2 \| \nabla u \|_{L^2(\mathbb{R}^3)}^2\), \(C_2(t) = CU \| \nabla u \|_{L^2(\mathbb{R}^3)}^2\) and \(C_3(t) = C \nu^{-1} r^{-2a} \| u \|_{L^2(\mathbb{R}^3)}^{4 - 2a} \| u \|_{L^2(\mathbb{R}^3)}^{2a}\). The positive functions \(C_1(t), C_2(t)\) and \(C_3(t)\) are known to be time-integrable. The interested reader can check that the inequality above is dimensionally correct, each term has dimensions of \([L]^6[T]^{-4}\). Then it follows that
\[
y^2 \frac{dy}{1 + y} \, dt \leq C_1(t) + C_2(t) + C_3(t),
\]
(no longer dimensionally correct), and after an easy integration, it follows that \(y\) is bounded a priori in time. This proves the first criterion.

For the proof of the second criterion we again represent \(p = \pi(x, r) + \beta(x, r)\) with \(r = r(t)\) and bound the integral involving \(\pi\) using straightforward integration by parts and Hölder inequalities:
\[
\left| \int_{\mathbb{R}^3} (u \cdot \nabla \pi) |u| \, dx \right| = \left| \int_{\mathbb{R}^3} \pi (u \cdot \nabla |u|) \, dx \right|
\]
\[
\leq \frac{\nu}{2} \int_{\mathbb{R}^3} |u| \| \nabla u \| \, dx + \frac{C}{\nu} \| u \|_{L^3(\mathbb{R}^3)} \| \pi \|_{L^2(\mathbb{R}^3)}^2.
\]
We bound the contribution coming from $\beta$ the same way as we did for the first criterion. The upshot is that $y(t) = \|u\|_{L^3(\mathbb{R}^3)}$ obeys

$$y^2 \frac{dy}{dt} \leq C_4(t)y + C_3(t)y$$

with $C_4(t) = \frac{C}{\nu}\|\pi\|_{L^3(\mathbb{R}^3)}^2$ which is time-integrable by assumption. It follows again that $y(t)$ is bounded apriori in time.

6. Appendix

We prove here the identities (5) and (6). We introduce polar coordinates,

$$\xi_1 = \rho \cos \phi \sin \theta = \rho c \sin \theta,$$

$$\xi_2 = \rho \sin \phi \sin \theta = \rho s \sin \theta,$$

$$\xi_3 = \rho \cos \theta = \rho C$$

where for simplicity of notation we abbreviate $s = \sin \phi$, $S = \sin \theta$, $c = \cos \phi$, $C = \cos \theta$. For a function on the unit sphere $\rho = 1$. But in general $f(\xi) = f(\rho c \sin \theta, \rho s \sin \theta, \rho C)$, and we have

$$f_\theta = \partial_\theta f = \rho (c C f_1 + s C f_2 - S f_3),$$

$$f_\phi = \partial_\phi f = \rho (-s S f_1 + c S f_2),$$

$$\rho f_\rho = \rho \partial_\rho f = \rho (c S f_1 + s S f_2 + C f_3)$$

where $\rho \partial_\rho f = \xi \cdot \nabla_\xi f$ and $\nabla_\xi f = (f_1, f_2, f_3)$. We note that $\rho \partial_\rho (\frac{\xi}{|\xi|}) = 0$, for $\xi \neq 0$. We have

$$C f_\theta + S \rho f_\rho = \rho (c f_1 + s f_2)$$

and thus

$$\rho f_1 = c (C f_\theta + S \rho f_\rho) - \frac{c}{s} f_\phi,$$

$$\rho f_2 = s (C f_\theta + S \rho f_\rho) + \frac{c}{s} f_\phi,$$

$$\rho f_3 = C \rho f_\rho - S f_\theta$$

(71)

We consider now $\rho = 1$ and denote for simplicity $D_\rho = \rho \partial_\rho$. We compute first

$$\int_{|\xi|=1} \xi_1 \partial_1 f(x + r \xi) dS(\xi)$$

using of course

$$dS(\xi) = S d\phi d\theta.$$

We have

$$\xi_1 \partial_{\xi_1} f = c S (c (C \partial_\theta + S D_\rho) - \frac{s}{S} \partial_\phi) f$$

$$= D_\rho (\xi_1^2) f + c^2 S C \partial_\theta f - sc \partial_\phi f.$$
We used the fact that on the unit sphere $\xi = \frac{x}{|x|}$ and $D_\rho(\xi) = 0$. We multiply by $S$ and integrate, integrating by parts where possible. In view of

$$-c^2 \frac{d}{d\theta}(S^2 C) = c^2 S(S^2 - 2C^2) = c^2 S(3S^2 - 2)$$

and

$$S \frac{d}{d\phi}(sc) = 2c^2 S - S,$$

the coefficients of $f$ are obtained by adding

$$c^2 S(3S^2 - 2) + 2c^2 S - S = S(3\xi_1^2 - 1),$$

and so

$$f_{|\xi|=1} \xi_1 \partial_\xi f dS(\xi) = f_{|\xi|=1} [D_\rho(\xi_1^2 f) + 3\xi_1^2 f - f] dS(\xi)$$

$$= D_\rho \left[ f_{|\xi|=1} \xi_1^2 f dS(\xi) \right] + f_{|\xi|=1}(3\xi_1^2 - 1) f dS(\xi)$$

which is the first relation in (5). The rest of the formulas in (5) are proved similarly. Indeed,

$$\xi_2 \partial_{\xi_2} f = sS \left[ s(C \partial_\theta + SD_\rho) + \frac{c}{2} \partial_\theta \right] f$$

$$= [s^2 S^2 D_\rho + s^2 SC \partial_\theta + sc \partial_\phi] f$$

Upon multiplication by $S$ and integration by parts in the $\partial_\theta$ and $\partial_\phi$ terms we obtain the coefficients of $f$

$$-s^2 \frac{d}{d\theta} (S^2 C) = s^2 S(3S^2 - 2) + S - 2c^2 S$$

$$= s^2 S(3S^2 - 2) - S + 2s^2 S = (3\xi_2^2 - 1) S$$

and therefore

$$f_{|\xi|=1} \xi_2 \partial_{\xi_2} f dS(\xi) =$$

$$D_\rho \left[ f_{|\xi|=1} \xi_2^2 f dS(\xi) \right] + f_{|\xi|=1}(3\xi_2^2 - 1) f dS(\xi)$$

like above. The third term is

$$\xi_3 \partial_3 f = C(CD_\rho - S\partial_\theta) f.$$

Multiplying by $S$ and integrating by parts the $\partial_\theta$ term, we compute the coefficient of $f$

$$\frac{d}{d\theta} (CS^2) = (3C^2 - 1) S = (3\xi_3^2 - 1),$$

and therefore we obtain the last relation of (5)

$$f_{|\xi|=1} \xi_3 \partial_{\xi_3} f dS(\xi) =$$

$$D_\rho \left[ f_{|\xi|=1} \xi_3^2 f dS(\xi) \right] + f_{|\xi|=1}(3\xi_3^2 - 1) f dS(\xi).$$
We prove now similarly the relations (6). We start with the term corresponding to the indices (1, 3):

\[
(\xi_1 \partial_{\xi_1} + \xi_3 \partial_{\xi_3}) f = \\
[cS(CD_\rho - S \partial_\theta) + C(c(C \partial_\theta + SD_\rho) - \frac{c}{S} \partial_\phi)] f = \\
[2cSCD_\rho + (cC^2 - cS^2) \partial_\theta - \frac{c \rho}{S} \partial_\phi] f
\]

Multiplying by \( S \), integrating, and integrating by parts we obtain the coefficient of \( f \) via

\[
-c \frac{d}{d\theta} (S(1 - 2S^2)) + C \frac{d}{d\phi} (s) \\
= -c(C - 6S^2 C) + Cc = 6cSCS = 6\xi_1 \xi_3 S
\]

and so

\[
\int_{|\xi|=1} (\xi_1 \partial_{\xi_1} + \xi_3 \partial_{\xi_3}) f dS(\xi) \\
= \int_{|\xi|=1} [2\xi_1 \xi_3 D_\rho f + 6\xi_1 \xi_3 f] dS(\xi) \\
= D_\rho \left[ \int_{|\xi|=1} 2\xi_1 \xi_3 f dS(\xi) \right] + \int_{|\xi|=1} 6\xi_1 \xi_3 f dS(\xi)
\]

which is the (1, 3) relation in (6). At indices (1, 2) we have to compute

\[
(\xi_1 \partial_2 + \xi_2 \partial_1) f \\
= [cS(sSD_\rho + sC \partial_\theta + \frac{c}{S} \partial_\phi) + sS(cSD_\rho + cC \partial_\theta - \frac{c}{S} \partial_\phi)] f \\
= 2cSsSD_\rho f + 2cs(SC) \partial_\theta f + (c^2 - s^2) \partial_\phi f.
\]

Multiplying by \( S \) and integrating by parts, we obtain the coefficient of \( f \) via

\[
-2cs \frac{d}{d\theta} (S^2 C) - S \frac{d}{d\phi} (c^2 - s^2) = \\
2cs(S^3 - 2SC^2) + 4SCs = 2cs(S^3 - 2S + 2S^3) + 4csS = 6csS^3
\]

\[
= 6\xi_1 \xi_2 S.
\]

We obtained thus

\[
\int_{|\xi|=1} (\xi_1 \partial_{\xi_2} + \xi_2 \partial_{\xi_1}) f dS(\xi) \\
= \int_{|\xi|=1} [2\xi_1 \xi_2 D_\rho f + 6\xi_1 \xi_2 f] dS(\xi) \\
= D_\rho \left[ \int_{|\xi|=1} 2\xi_1 \xi_2 f dS(\xi) \right] + \int_{|\xi|=1} 6\xi_1 \xi_2 f dS(\xi)
\]

which is the (1, 2) relation of (6). Finally, at (2, 3) we have to compute

\[
(\xi_2 \partial_3 + \xi_3 \partial_2) f = sS(CD_\rho - S \partial_\theta) f + C(sSD_\rho + sC \partial_\theta + \frac{c}{S} \partial_\phi) f \\
= 2sSCD_\rho f + (s(C^2 - S^2) \partial_\theta + C \frac{c}{S} \partial_\phi) f.
\]

Multiplying by \( S \) and integrating by parts, the coefficient of \( f \) is computed via

\[
-s \frac{d}{d\theta} (S(C^2 - S^2)) - C \frac{d}{d\phi} c = \\
s(6S^2 C - C) + Cs = 6sSCS = 6\xi_2 \xi_3 S
\]
and we obtain thus

\[ \int_{|\xi|=1} (\xi_2 \partial_3 + \xi_3 \partial_2) f dS(\xi) \]
\[ = \int_{|\xi|=1} [2\xi_2 \xi_3 D_\rho f + 6\xi_2 \xi_3 f] dS(\xi) \]
\[ = D_\rho \left[ \int_{|\xi|=1} 2\xi_2 \xi_3 f dS(\xi) \right] + \int_{|\xi|=1} 6\xi_2 \xi_3 f dS(\xi) \]

which is the (2, 3) relation of (6).
