INDUCED SUBGRAPHS AND TREE DECOMPOSITIONS
IX. GRID THEOREM FOR PERFORATED GRAPHS

BOGDAN ALECU∗∗¶, MARIA CHUDNOVSKY∗∗⨿, SEPEHR HAJEBI§, AND SOPHIE SPIRKŁ∥

Abstract. The celebrated Erdős-Pósa Theorem, in one formulation, asserts that for every
$c \geq 1$, graphs with no subgraph (or equivalently, minor) isomorphic to the disjoint union of $c$
cycles have bounded treewidth. What can we say about the treewidth of graphs containing no
induced subgraph isomorphic to the disjoint union of $c$ cycles?

Let us call these graphs $c$-perforated. While $1$-perforated graphs have treewidth one, complete
graphs and complete bipartite graphs are examples of $2$-perforated graphs with arbitrarily large
treewidth. But there are sparse examples, too: Bonamy, Bonnet, Déprés, Esperet, Geniet,
Hilaire, Thomassé and Wesolek constructed $2$-perforated graphs with arbitrarily large treewidth
and no induced subgraph isomorphic to $K_3$ or $K_{3,3}$; we call these graphs occultations. Indeed,
it turns out that a mild (and inevitable) adjustment of occultations provides examples of $2$-
perforated graphs with arbitrarily large treewidth and arbitrarily large girth, which we refer to
as full occultations.

Our main result shows that the converse also holds: for every $c \geq 1$, a $c$-perforated graph
has large treewidth if and only if it contains, as an induced subgraph, either a large complete
graph, or a large complete bipartite graph, or a large full occultation. This distinguishes
$c$-perforated graphs, among graph classes purely defined by forbidden induced subgraphs, as the
first to admit a grid-type theorem incorporating obstructions other than subdivided walls and
their line graphs.

More generally, for all $c, o \geq 1$, we establish a full characterization of induced subgraph
obstructions to bounded treewidth in graphs containing no induced subgraph isomorphic to the
disjoint union of $c$ cycles, each of length at least $o + 2$.

1. Introduction

1.1. Background. Graphs in this paper have finite vertex sets, no loops and no parallel edges.
Let $G = (V(G), E(G))$ be a graph. For $X \subseteq V(G)$, we denote by $G[X]$ the subgraph of $G$
induced by $X$. In this paper, we use induced subgraphs and their vertex sets interchangeably.
For graphs $G$ and $H$, we say $G$ contains $H$ if $G$ has an induced subgraph isomorphic to $H$, and
we say $G$ is $H$-free if $G$ does not contain $H$. A class of graphs is hereditary if it is closed under
isomorphism and taking induced subgraphs.

A tree decomposition of a graph $G$ is a pair $(T, \chi)$ where $T$ is a tree and $\chi : V(T) \to 2^{V(G)}$ is
a map which satisfies the following:

(i) For every $v \in V(G)$, there exists $t \in V(T)$ such that $v \in \chi(t)$.
(ii) For every $v_1 v_2 \in E(G)$, there exists $t \in V(T)$ such that $v_1, v_2 \in \chi(t)$.
(iii) For every $v \in V(G)$, the subgraph of $T$ induced by $\{t \in V(T) : v \in \chi(t)\}$ is connected.

The width of a tree decomposition \((T, \chi)\) is \(\max_{t \in V(T)} |\chi(t)| - 1\). The treewidth of \(G\), denoted by \(\text{tw}(G)\), is the minimum width of a tree decomposition of \(G\).

The systematic study of treewidth was originated by Robertson and Seymour as a highlight of their graph minors project. Roughly speaking, graphs of small treewidth are “measurably fattened forests.” This brings on a wealth of nice structural [17] and algorithmic [5] properties for them, which partly explains the enduring popularity of the subject, as well. It also motivates understanding graphs of large treewidth. In particular, it is of enormous interest to identify graph classes in which large treewidth can be certified “locally” by a subconfiguration, still of (relatively) large treewidth yet structurally simpler than the host graph. The prototypical result of this sort is the foundational “Grid Theorem” of Robertson and Seymour [17], Theorem 1.1 below, which characterizes all subgraph-closed (and also minor-closed) graph classes of bounded treewidth. In effect, the Grid Theorem says that every graph of sufficiently large treewidth contains as a subgraph some subdivision of a highly symmetrical graph of large treewidth called a “wall.” For an integer \(t \geq 1\), we denote by \(W_{t \times t}\) the \((t \times t)\)-wall, which is (almost) the \(t\)-by-\(t\) hexagonal grid, and has treewidth \(t\) (see Figure 1; a full definition can be found in [2]).

**Theorem 1.1** (Robertson and Seymour [17]). For every integer \(t \geq 1\), there exists \(w = w(t) \geq 1\) such that every graph of treewidth more than \(w\) contains \(W_{t \times t}\) as a minor, or equivalently, a subdivision of \(W_{t \times t}\) as a subgraph.

What could be a “Grid Theorem” for induced subgraphs? This question lies at the heart of a recent trend in structural graph theory, which aims at bridging the gap between the two pillars of the subject: graph minors and the theory of induced subgraphs. Despite the immense body of research in both areas, however, the above question remains wide open, to the extent that (more or less) the only reliable clue at the moment is provided by the “basic obstructions,” which are known to have arbitrarily large treewidth; in fact, for an integer \(t \geq 1\), the complete graph \(K_{t+1}\), the complete bipartite graph \(K_{t,t}\), all subdivisions of \(W_{t \times t}\) mentioned above, or the line graph of a subdivision of \(W_{t \times t}\), where the line graph \(L(F)\) of a graph \(F\) is the graph with vertex set \(E(F)\), such that two vertices of \(L(F)\) are adjacent if the corresponding edges of \(F\) share an end. The basic obstructions are known to have arbitrarily large treewidth; in fact, for an integer \(t \geq 1\), the complete graph \(K_{t+1}\), the complete bipartite graph \(K_{t,t}\), all subdivisions of \(W_{t \times t}\) and line graphs of all subdivisions of \(W_{t \times t}\) all have treewidth \(t\). So an exhaustive list of unavoidable induced subgraphs of graphs with large treewidth must contain, for some \(t\), an induced subgraph of a \(t\)-basic obstruction of each type. It is also of note that there are hereditary classes for which the basic obstructions do comprise a full list of induced subgraph obstructions to bounded treewidth. We call such classes “clean.” In technical terms, for an integer \(t \geq 1\), we say a graph \(H\) is a \(t\)-basic obstruction if \(H\) is either the complete graph \(K_t\), or the complete bipartite graphs \(K_{t,t}\), or a subdivision of \(W_{t \times t}\) mentioned above, or the line graph of a subdivision of \(W_{t \times t}\), where the line graph \(L(F)\) of a graph \(F\) is the graph with vertex set \(E(F)\), such that two vertices of \(L(F)\) are adjacent if the corresponding edges of \(F\) share an end. The basic obstructions are known to have arbitrarily large treewidth; in fact, for an integer \(t \geq 1\), the complete graph \(K_{t+1}\), the complete bipartite graph \(K_{t,t}\), all subdivisions of \(W_{t \times t}\) and line graphs of all subdivisions of \(W_{t \times t}\) all have treewidth \(t\). So an exhaustive list of unavoidable induced subgraphs of graphs with large treewidth must contain, for some \(t\), an induced subgraph of a \(t\)-basic obstruction of each type. It is also of note that there are hereditary classes for which the basic obstructions do comprise a full list of induced subgraph obstructions to bounded treewidth. We call such classes “clean.” In technical terms, for an integer \(t \geq 1\), we say a graph \(G\) is \(t\)-clean if \(G\) does not contain a \(t\)-basic obstruction. A graph class \(C\) is clean if for every integer \(t \geq 1\), there exists an integer \(w(t) \geq 1\) (depending on \(C\)) such that every \(t\)-clean graph in \(G\) has treewidth at most \(w(t)\). For instance, Korhonen [13] proved that every graph class of bounded maximum degree is clean. With Abrishami, we recently extended this to a full characterization of graphs \(H\) for which the class of \(H\)-free graphs is clean:
Theorem 1.2 (Abrishami, Alecu, Chudnovsky, Hajebi and Spirkl [1]). The class of all $H$-free graphs is clean if and only if $H$ is a subdivided star forest, that is, a forest in which every component has at most one vertex of degree more than two.

Nevertheless, as mentioned earlier, the basic obstructions cannot carry all the load. There are at least three constructions certifying this fact. We list them below in the chronological order of discovery. They all consist of graphs with arbitrarily large treewidth which are 3 or 4-clean, and the third one is central to the context of this paper, which we will elaborate on later.

- The so-called “layered-wheels” of Sintiari and Trotignon [18] consisting of even-clean graphs and theta-free graphs.
- A construction first popularized by Davies [7], also found earlier by Pohoata [15].
- A construction by Bonamy, Bonnet, Déprés, Esperet, Geniet, Hilaire, Thomassé and Wesolek [6], consisting of graphs with “bounded induced cycle packing number.”

All of this goes to show that an ultimate Grid Theorem for induced subgraphs must encompass some “non-basic obstructions,” an exact description of which remains unknown. More dramatically, until now there was no hereditary class for which there is a Grid Theorem involving any non-basic obstruction. Our main result introduces the first such class.

1.2. Motivation and (a taste of) the main result. In order to formally state our main result, Theorem 3.2, we need quite a few definitions, and so we postpone it to Section 3. Instead, our goal here is to motivate Theorem 3.2 and give the exact statement of a weakening that captures its essence. This takes a brief digression to the world of the “Erdős-Pósa Theorem.”

Observe that graphs with no subgraph isomorphic to a cycle are forests, which in turn are exactly the graphs with treewidth 1. Erdős and Pósa famously extended this simple fact to graphs excluding the disjoint union of any prescribed number of cycles as a subgraph, showing that such graphs remain proportionately close to being a forest:

Theorem 1.3 (Erdős and Pósa [9]). For every integer $c \geq 1$, there exists an integer $h \geq 0$ such that in every graph $G$ with no subgraph (or equivalently, minor) isomorphic to the disjoint union of $c$ cycles, there exists a subset $X \subseteq G$ with $|X| \leq h$ such that $G \setminus X$ is a forest.

It follows that, for every integer $c \geq 1$, graphs with no subgraph isomorphic to the disjoint union of $c$ cycles have bounded treewidth (this is in fact equivalent to Theorem 1.3; see [17]). It is therefore natural to ask: what can be said about the treewidth of graphs with no induced subgraph isomorphic to the disjoint union of many cycles? For an integer $c \geq 1$, we say a graph $G$ is $c$-perforated if $G$ does not contain (as an induced subgraph) the disjoint union of $c$ cycles. Then 1-perforated graphs still have treewidth 1. However, even for 2-perforated graphs, bounded treewidth is far from a realistic expectation: for every integer $t \geq 1$, the complete graph $K_t$ and the complete bipartite graph $K_{t,t}$ are both 2-perforated basic obstructions. In contrast, sufficiently large subdivided walls and their line graphs are easily seen not to be $c$-perforated for any $c \geq 1$.

One may then speculate that for all integers $c,t \geq 1$, every $c$-perforated graph containing neither $K_t$ nor $K_{t,t}$ has bounded treewidth. This turns out not to be true either, yet the reason is not as simple. Bonamy, Bonnet, Déprés, Esperet, Geniet, Hilaire, Thomassé and Wesolek [6] provided, for every integer $s \geq 1$, a beautiful construction of 2-perforated graphs with treewidth at least $s - 1$ and containing neither $K_3$ nor $K_{3,3}$. We call these graphs “$s$-occultations” and we will give a detailed description of them in a moment. But let us first state our main result: surprisingly enough, the above construction completes the picture of induced subgraph obstructions to bounded treewidth in $c$-perforated graphs for every $c$. More precisely, we introduce a slight modification of $s$-occultations called full $s$-occultations, and show that they are all we need to establish a Grid Theorem for $c$-perforated graphs:

Theorem 1.4. For all integers $c,t \geq 1$ and $s \geq 0$, there exists an integer $\tau = \tau(c,s,t) \geq 1$ such that every $c$-perforated graph of treewidth more than $\tau$ contains either $K_t$, or $K_{t,t}$, or a full $s$-occultation.
We remark that, to the best of our knowledge, Theorem 1.4 is the first of its kind, in the sense that it offers the first Grid Theorem for a hereditary class which involves non-basic obstructions (we also note a result from [11] which characterizes the induced subgraph obstructions to bounded treewidth in the class of “circle graphs,” though we view that more relatable in the context of “vertex-minors.”) More generally, the main result of this paper, Theorem 3.2, is an extension of Theorem 1.4 which completely describes, for all integers \( c, o \geq 1 \), the obstructions to bounded treewidth in \((c, o)\)-perforated graphs, that is, graphs with no induced subgraph isomorphic to the disjoint union of \( c \) cycles, each of length at least \( o + 2 \). The extension is in fact direct enough that Theorems 1.4 and 3.2 are identical when \( o = 1 \).

It is also worth mentioning that \( s \)-occultations were constructed in [6] mainly to show that the bound in their main result, Theorem 1.5 below, is asymptotically sharp. In view of Theorem 1.5, excluding complete graphs and complete bipartite graphs in \( c \)-perforated graphs does make a difference by bringing the treewidth down to being logarithmic in the number of vertices. This is of almost equal algorithmic significance as bounded treewidth, and also puts \( c \)-perforated graphs on the very short list of hereditary classes known to have logarithmic treewidth.

**Theorem 1.5** (Bonamy, Bonnet, Déprés, Esperet, Geniet, Hilaire, Thomassé and Wesolek [6]). For all integers \( c, t \geq 1 \), every \( c \)-perforated graph \( G \) containing neither \( K_t \) nor \( K_{t,t} \) has treewidth at most \( O(\log |V(G)|) \).

### 1.3. Occultations: first impression.

For an integer \( n \), we write \([n]\) for the set all of positive integers less than or equal to \( n \) (so \([n]\) = \( \emptyset \) if \( n \leq 0 \)). Let \( G \) be a graph. A **stable set in** \( G \) is a set of pairwise non-adjacent vertices. A **path in** \( G \) is an induced subgraph of \( G \) which is a path. If \( P \) is a path in \( G \), we write \( P = p_1 \cdots p_k \) to mean that \( V(P) = \{p_1, \ldots, p_k\} \) and \( p_i \) is adjacent to \( p_j \) if and only if \(|i - j| = 1\). We call the vertices \( p_1 \) and \( p_k \) the **ends** of \( P \), and the **interior** of \( P \) is the set \( P \setminus \{p_1, p_k\} \). The **length** of a path is its number of edges.

Let us now formally define occultations and full occultations. Given an integer \( s \geq 1 \), an **s-occultation** is a graph \( \mathcal{O} \) whose vertex set can be partitioned into a stable set \( S \) in \( \mathcal{O} \) of cardinality \( s \) and a path \( L \) in \( \mathcal{O} \) with the following specifications.

1. **No two vertices in** \( S \) have a common neighbor in \( V(L) \).
2. **The ends of** \( L \) have no neighbor in \( S \).
3. **For some bijection** \( \pi : [s] \to S \), the following holds. Let \( i \in [s] \) and let \( P \) be a path in \( L \) of non-zero length where
   - every end of \( P \) that is not an end of \( L \) has a neighbor in \( \pi([i - 1]) \); and
   - no vertex in the interior of \( P \) has a neighbor in \( \pi([i - 1]) \).
   Then \( \pi(i) \) has **exactly** one neighbor in the interior of \( P \). In particular, \( \pi(i) \) has exactly \( 2^{i-1} \) neighbors in \( L \) and \( P \) has non-empty interior. Said differently, along \( L \), \( \pi(i) \) has exactly one neighbour “between” every two successive vertices which are either an end of \( L \) or a neighbour of a vertex in \( \pi([i - 1]) \).
4. **No vertex in** \( L \) has degree 2 in \( \mathcal{O} \). In particular, \( L \) has length \( 2^s \).

See Figure 2. As mentioned before, these graphs were introduced in [6] for the first time\(^1\) to provide a lower bound counterpart to Theorem 1.5:

**Theorem 1.6** (Bonamy, Bonnet, Déprés, Esperet, Geniet, Hilaire, Thomassé and Wesolek [6]). For every integer \( s \geq 1 \), every \( s \)-occultation is a 2-perforated graph containing neither \( K_3 \) nor \( K_{3,3} \) and with treewidth at least \( s - 1 \).

Even so, the occultations defined above are not quite ready yet to be admitted as an outcome of a Grid Theorem for induced subgraphs. For instance, note that subdividing the edges of a graph \( G \) does not preserve subgraphs and induced subgraphs of \( G \), while it does not change the treewidth of \( G \) either. This is why the “subgraph version” of Theorem 1.1 as well as results

\(^1\)Not verbatim. Also, in their version no vertex in \( L \) is allowed to have degree 1 in \( \mathcal{O} \) (so it is obtained from our version by removing the ends of \( L \)). This clearly does not interfere with the validity of Theorem 1.6.
concerning clean classes like Theorem 1.2 deal with subdivided walls, as opposed to the “minor version” of Theorem 1.1 which involves bona fide walls. In the same vein, one may subdivide the edges of the path \( L \) in an occultation \( \sigma \), and observe that the resulting graph still satisfies Theorem 1.6. This, in other words, shows that we cannot require (O4) of an occultation-like obstruction which is expected to yield bounded treewidth when forbidden (in conjunction with the basic obstructions). Similarly, when it comes to extracting an occultation as an induced subgraph in a graph of large treewidth, the word “exactly” in (O3) is too much to ask.

Luckily, these two turn out to be the only culprits: we may define our “full occultations” to appear in Theorem 1.4 as graphs with literally the same definition as occultations, except the condition (O4) must be lifted, and the word “exactly” in (O3) must be replaced by “at least.”

More precisely, for an integer \( s \geq 0 \), a full \( s \)-occultation is a graph \( o \) where the vertex set of \( o \) can be partitioned into a stable set \( S \) of cardinality \( s \) and a path \( L \) in \( o \) with the following specifications.

\begin{itemize}
  \item [(FO1)] No two vertices in \( S \) have a common neighbor in \( L \).
  \item [(FO2)] The ends of \( L \) have no neighbor in \( S \).
  \item [(FO3)] For some bijection \( \pi : [s] \to S \), the following holds. Let \( i \in [s] \) and let \( P \) be a path in \( L \) of non-zero length where
    \begin{itemize}
      \item each end of \( P \) that is not an end of \( L \) has a neighbor in \( \pi([i-1]) \); and
      \item no vertex in the interior of \( P \) has a neighbor in \( \pi([i-1]) \).
    \end{itemize}
    Then \( \pi(i) \) has at least one neighbor in the interior of \( P \). In particular, \( \pi(i) \) has a neighbor in \( L \) and \( P \) has non-empty interior.
\end{itemize}

See Figure 3. As we will show in Theorem 3.1, the difference between occultations and full occultations is mild enough that it has almost no effect on Theorem 1.6 remaining true for full occultations. In fact, we will define full occultations once again in Section 3 using “asterisms,” a term we employ extensively in this paper as it is a great technical fit to our proofs. This in particular allows for upgrading to a parametrized relaxation of full \( s \)-occultations called “full \((s,o)\)-occultations,” which we then show to be the right substitute for full \( s \)-occultations in extending Theorem 1.4 to Theorem 3.2.

1.4. Outline. We now briefly describe our proof ideas and the organization of the paper. Broadly speaking, the proof of Theorem 1.4 (or Theorem 3.2, rather) consists of three steps.

Let \( G \) be a \( c \)-perforated graph of sufficiently large treewidth which contains neither \( K_t \) nor \( K_{t,t} \). We wish to show that \( G \) contains a full \( s \)-occultation.

First, we show that \( G \) contains a very large “constellation,” that is, a complete bipartite induced minor model where each “branch set” on one “side” is a vertex and each branch set on the other side is a path in \( G \). To that end, we invoke a useful result from an earlier paper in this series [1], namely Theorem 2.4, which, in essence, says that every graph class of bounded “local
connectivity” is clean. This allows us to obtain, for a very very large integer $M$, a collection of $M$ pairwise disjoint induced subgraphs $G_1, \ldots, G_M$ of $G$ such that for each $i$, one may find in $G_i$ two vertices $x_i$ and $y_i$ as well as, for another large integer $m$, a collection of $m$ pairwise internally disjoint (long) paths in $G_i$ from $x_i$ to $y_i$. From here, the proof goes on a roller coaster ride of Ramsey-type arguments to show that if $G$ excludes the desired constellation, then there are $c$ distinct $G_i$’s in each of which one may find a (long) induced cycle $H_i$, with no edges in $G$ between distinct $H_i$’s. But this violates the assumption that $G$ is $c$-perforated.

Next, we show that if $G$ contains a huge constellation, then $G$ contains an approximate version of a full occultation called an “interrupted asterism,” in which (FO3) is guaranteed to hold only if the ends of the path $P$ have no common neighbor in $S$. Here is an intuitive exposition of the argument: note that for each path $L$ in the “path side” $\mathcal{L}$ of the constellation, one may define a graph on the “vertex side” $V$ called the “transition graph” by making two vertices in $V$ adjacent if there is a “route” $R$ in $G$ between them with its interior contained in $L$ such that no other vertex in $V$ has a neighbor in the interior of $R$. Then we can easily arrange for most paths in $L$ to impose the same transition graph $T$ on $V$. There are now two possibilities. If $T$ contains a matching of cardinality $c$, then the union of corresponding routes through two distinct paths in $\mathcal{L}$ gives a collection of $c$ pairwise disjoint cycles in $G$ with no edges between them, which is impossible. It follows that $T$ admits a small vertex cover $X \subseteq V$. From the definition of the transition graph, every route between two distinct vertices in $V \setminus X$ must be “interrupted” by a neighbor of a vertex in $X$. But now $X$ starts to behave like the vertex $\pi(s)$ from the definition of a full s-occultation (up to the above-mentioned relaxation of (FO3)), which we can delete and move on by induction on $s$. This of course takes much more work to make precise.

Third, we turn the approximate full occultation obtained in the second step into a genuine one. To accomplish this, we need the “interrupted” asterism to be “invaded” as well, which means (FO3) is now required to hold even if the ends of $P$ have a common neighbor in $S$. 

Figure 3. A full 4-occultation: circled nodes from top to bottom represent $\pi(4), \pi(3), \pi(2)$ and $\pi(1)$, and the rest depict vertices in $L$. For the sake of clarity, the neighbors of $\pi(i)$ in $L$ are labeled $i$ for each $i \in [4]$. Dotted lines represent paths of arbitrary non-zero length (the union of which is $L$).
Otherwise, the union of $P$ and the common neighbor of its ends in $S$ form an induced cycle $H$ in $G$, and we can convince a “big” portion of the rest of the asterism to be disjoint from $H$ and have no neighbors in $H$, and then proceed by induction on $c$. This makes the last step, again, modulo a fair body of details to be checked, relatively easier than the previous two.

The technical circumstances of our proofs, however, demand for these three steps to be taken in reverse order in Sections 4, 6 and 7, while Section 5 will be our Ramsey workout to prepare for the next two sections. In Section 2, we set up our terminology and gather a few results from the literature to be used in subsequent sections. Section 3 is devoted to asterisms and the statement of our main result, Theorem 3.2. Finally, in Section 8, we complete the proof of Theorem 3.2.

2. Preliminaries

Let $G = (V(G), E(G))$ be a graph. For $X \subseteq V(G) \cup E(G)$, $G \setminus X$ denotes the subgraph of $G$ obtained by removing $X$. Note that if $X \subseteq V(G)$, then $G \setminus X$ denotes the subgraph of $G$ induced by $V(G) \setminus X$.

Let $P$ be a path in $G$. We denote by $P^\circ$ the interior of $P$ and by $\partial P$ the set of ends of $P$. Similarly, for a collection $\mathcal{P}$ of paths in $G$, we adapt the notations $V(\mathcal{P}) = \bigcup_{P \in \mathcal{P}} V(P)$, $\mathcal{P}^\circ = \bigcup_{P \in \mathcal{P}} P^\circ$ and $\partial \mathcal{P} = \bigcup_{P \in \mathcal{P}} \partial P$.

A cycle in $G$ is an induced subgraph of $G$ that is a cycle. If $H$ is a cycle in $G$, we write $H = c_1, \ldots, c_k$ to mean that $V(C) = \{c_1, \ldots, c_k\}$ and $c_i$ is adjacent to $c_j$ if and only if $|i - j| \in \{1, k - 1\}$. The length of a cycle is its number of edges.

Let $x \in V(G)$. We denote by $N_G(x)$ the set of all neighbors of $x$ in $G$, and by $N_G[x]$ the set $N_G(x) \cup \{x\}$. A cycle $H$ of $G$ is an induced subgraph of $G$, we define $N_H(x) = N_G(x) \cap H$, $N_H[x] = N_G[x] \cap H$. Also, for $X \subseteq G$, we denote by $N_G(X)$ the set of all vertices in $G \setminus X$ with at least one neighbor in $X$, and define $N_G[X] = N_G(X) \cup X$.

Let $X, Y \subseteq V(G)$ be disjoint. We say $X$ is complete to $Y$ if all edges with an end in $X$ and an end in $Y$ are present in $G$, and $X$ is anticomplete to $Y$ if no edges between $X$ and $Y$ are present in $G$.

By a subdivision of $G$, we mean a graph $G'$ obtained from $G$ by replacing the edges of $G$ by pairwise internally disjoint paths of non-zero length between the corresponding ends, and these ends will be referred to as the pinned vertices of $G'$ (so the pinned vertices of $G'$ are in fact the original vertices of $G$). Let $r \geq 0$ be an integer. A $(\leq r)$-subdivision of $G$ is a subdivision of $G$ in which the path replacing each edge has length at most $r + 1$.

Let us now mention a few results from the literature, beginning with two versions of Ramsey’s Theorem. Given a set $X$ and an integer $q \geq 0$, we denote by $2^X$ the power set of $X$ and by $\binom{\binom{q}{2}}{q}$ the set of all $q$-subsets of $X$.

**Theorem 2.1** (Ramsey [16]). For all integers $n \geq 0$ and $q, r \geq 1$, there exists an integer $\rho(n, q, r) \geq 1$ with the following property. Let $U$ be a set of cardinality at least $\rho(n, q, r)$ and let $W$ be a non-empty set of cardinality at most $r$. Let $\Phi : \binom{U}{q} \to W$ be a map. Then there exist $i \in W$ and $Z \subseteq U$ with $|Z| = n$ such that for every $A \in \binom{Z}{q}$, we have $\Phi(A) = i$.

**Theorem 2.2** (Graham, Rothschild and Spencer [10], see also [12]). For all integers $n \geq 0$ and $q, r \geq 1$, there exists an integer $\nu(n, q, r) \geq 1$ with the following property. Let $U_1, \ldots, U_n$ be $n$ sets, each of cardinality at least $\nu(n, q, r)$ and let $W$ be a non-empty set of cardinality at most $r$. Let $\Phi$ be a map from the Cartesian product $U_1 \times \cdots \times U_n$ into $W$. Then there exist $i \in W$ and $Z_j \subseteq U_j$ with $|Z_j| = q$ for each $j \in [n]$, such that for every $z \in Z_1 \times \cdots \times Z_n$, we have $\Phi(z) = i$.

We also need the following result, which is a direct consequence of Theorem 5 in [8]. See also Theorem 3 in [14], which has been discovered after – and follows from – Theorem 5 in [8].

**Theorem 2.3** (Dvořák, see Theorem 6 in [8], Lozin and Razgon, see Theorem 3 in [14]). For every graph $H$ and all integers $d \geq 0$ and $t \geq 1$, there exists an integer $m = m(H, d, t) \geq 1$ with the following property. Let $G$ be a graph with no induced subgraph isomorphic to a subdivision of...
Assume that $G$ contains a $(\leq d)$-subdivision of $K_m$ as a subgraph. Then $G$ contains either $K_t$ or $K_{t,t}$.

Let $k \geq 1$ be an integer and let $G$ be a graph. A strong $k$-block in $G$ is a set $B$ of at least $k$ vertices in $G$ such that for every 2-subset $\{x,y\}$ of $B$, there exists a collection $P_{\{x,y\}}$ of at least $k$ distinct and pairwise internally disjoint paths in $G$ from $x$ to $y$, where for every two distinct 2-subsets $\{x,y\}, \{x',y'\} \subseteq B$ of $G$, we have $V(P_{\{x,y\}}) \cap V(P_{\{x',y'\}}) = \{x,y\} \cap \{x',y'\}$.

In [1], with Abrishami we proved the following:

**Theorem 2.4** (Abrishami, Alecu, Chudnovsky, Hajebi and Spirkl [1]). Let $k, t \geq 1$ be integers. Then there exists an integer $w = w(k, t) \geq 1$ such that every $t$-clean graph with no strong $k$-block has treewidth at most $w$.

Given a graph $G$ and an integer $d \geq 1$, a $d$-stable set in $G$ is a set $S \subseteq V(G)$ such that for every two distinct vertices $u, v \in S$, there is no path of length at most $d$ in $G$ from $u$ to $v$. It is proved in [1] that:

**Theorem 2.5** (Abrishami, Alecu, Chudnovsky, Hajebi and Spirkl [1]). For all integers $d, k \geq 1$ and $m \geq 2$, there exists an integer $\kappa = \kappa(d,k,m) \geq 1$ with the following property. Let $G$ be a graph and $B$ be a strong $\kappa$-block in $G$. Assume that $G$ does not contain a $(\leq d)$-subdivision of $K_m$ as a subgraph. Then there exists $A \subseteq G$ with $B' \subseteq B \setminus A$ such that $B'$ is both a strong $k$-block and a $d$-stable set in $G \setminus A$.

For integers $c, o \geq 1$, a graph $G$ is said to be $(c, o)$-perforated if there are no $c$ pairwise disjoint cycles in $G$, each of length at least $o + 2$. It follows that $G$ is $c$-perforated if and only if $G$ is $(c, 1)$-perforated. Also, one may observe that subdivisions of $W_{5co \times 5co}$ and their line graphs are not $(c, o)$-perforated. It follows from Theorem 2.4 that:

**Corollary 2.6.** For all integers $c, k, o, t \geq 1$, there exists an integer $\xi = \xi(c, k, o, t)$ such that every $(c, o)$-perforated graph of treewidth more than $\xi$ contains either $K_t$, or $K_{t,t}$, or a strong $k$-block.

A vertex $v$ in a graph $G$ is said to be a branch vertex if $v$ has degree more than two. By a caterpillar we mean a tree $T$ with maximum degree three such that there is a path $P$ in $T$ containing all branch vertices of $T$ (this is not standard for two reasons: a caterpillar is usually allowed to be of arbitrary maximum degree, and the path $P$ from the definition often contains all vertices of degree more than one). By a subdivided star we mean a graph isomorphic to a subdivision of the complete bipartite graph $K_{1,\delta}$ for some $\delta \geq 3$. In other words, a subdivided star is a tree with exactly one branch vertex, which we call its root. For a graph $H$, a vertex $v$ of $H$ is said to be simplicial if $N_H(v)$ is a clique in $G$. We denote by $Z(H)$ the set of all simplicial vertices of $H$. Note that for every tree $T$, $Z(T)$ is the set of all leaves of $T$. Also, if $H$ is the line graph of a tree $T$, then $Z(H)$ is the set of all vertices in $H$ corresponding to the edges in $T$ which are incident with the leaves of $T$. The following is proved in [1]:

**Theorem 2.7** (Abrishami, Alecu, Chudnovsky, Hajebi and Spirkl [1]). For every integer $h \geq 1$, there exists an integer $\mu = \mu(h) \geq 1$ with the following property. Let $G$ be a connected graph with no clique of cardinality $h$ and let $S \subseteq G$ such that $|S| \geq \mu$. Then there is an induced subgraph $H$ of $G$ with $|H \cap S| = h$ for which one of the following holds.

(a) $H$ is a path in $G$.

(b) $H$ is either a caterpillar or the line graph of a caterpillar with $H \cap S = Z(H)$.

(c) $H$ is a subdivided star with root $z$ such that $Z(H) \subseteq H \cap S \subseteq Z(H) \cup \{z\}$.

3. Asterisms

In this section, we state our main result in formal terms, beginning with a definition which is of critical importance in the remainder of this paper. Let $G$ be a graph and let $s \geq 0$ be an integer. By an $s$-asterism in $G$ we mean a pair $a = (S_a, L_a)$ where $S_a$ is a stable set in $G$ with
Figure 4. A 2-ample 4-asterism $a$ with $S_a = \{x_1, x_2, x_3, x_4\}$ and
$L = u_1 \cdots u_{23}$. For instance, $x_1$-u$_7$-u$_6$-u$_5$-x$_2$ is an $a$-route, $u_{13}$-u$_{14}$-u$_{15}$-u$_{16}$ is an open $a$-piece and $u_{20}$-u$_{21}$ is a closed $a$-piece.

$|S_a| = s$ and $L_a$ is a path in $G \setminus S_a$, such that every vertex in $S_a$ has a neighbor in $L_a^*$ and $S_a$ is anticomplete to $\partial L_a$. An ordered $s$-asterism in $G$ consists of an $s$-asterism $a$ along with a bijection $\pi_a : [s] \to S_a$. There are several convenient notations and definitions associated with asterisms, and we prefer to collect them all below. See also Figure 4.

Fix an (ordered) $s$-asterism $a$ in $G$. We denote by $V(a)$ the vertex set $S_a \cup V(L_a)$. By an $a$-route we mean a path in $G$ with ends in $S_a$ and interior contained in $L_a$. An $a$-route $R$ is minimal if there is no $a$-route $Q$ with $Q^*$ properly contained in $R^*$. We say $a$ is ample if no two vertices in $S_a$ have a common neighbor in $L_a$. More generally, given an integer $d \geq 0$, we say $a$ is d-ample if every $a$-route has length at least $d + 2$. For instance, every asterism in $G$ is 0-ample, and $a$ is 1-ample if and only if $a$ is ample.

By an $a$-piece we mean a path $P$ in $L_a$ of non-zero length such that every end of $P$ is not an end of $L_a$ has a neighbor in $S_a$, and $P^*$ is anticomplete to $S_a$. An $a$-piece $P$ is internal if $P$ is contained in $L_a^*$; otherwise $P$ is external (so the entire path $L_a$ is the only external $a$-piece if $S_a = \emptyset$, there are exactly two external $a$-pieces if $S_a \neq \emptyset$). An $a$-piece $P$ is said to be open if the ends of $P$ have no common neighbor in $S_a$, and closed if the ends of $P$ have a common neighbor in $S_a$. It follows that every external $a$-piece is open. In fact, one may observe that an $a$-piece $P$ is open if an only if either $P$ is external or $P$ is the interior of a minimal $a$-route.

For every subset $X$ of $S_a$, we denote by $a|X$ the (ordered) $|X|$-asterism $(X, L_a)$ such that, in case $a$ is ordered, for all distinct $x, x' \in X$, we have $\pi_{a|X}(x) > \pi_{a|X}(x')$ if and only if $\pi_a(x) > \pi_a(x')$.

Assume that $a$ is ordered. For every integer $i$, we write $a^i = a|\pi_a([i])$. We say $a$ is interrupted if for every $i \in [s]$:

- (INT) $\pi_a(i)$ has at least one neighbor in every open $a^{i-1}$-piece.

Also, we say $a$ is invaded if for every $i \in [s]$:

- (INV) $\pi_a(i)$ has at least one neighbor in every closed $a^{i-1}$-piece.

Let us now re-define full occultations in terms of asterisms. Given a graph $G$ and an integer $s \geq 0$, a full $s$-occultation in $G$ is an ample ordered $s$-asterism $a$ in $G$ which is both interrupted and invaded, that is, for every $i \in [s]$, $\pi_a(i)$ has at least one neighbor in the interior of every $a^{i-1}$-piece. It is straightforward to check that this definition is equivalent to the one mentioned in Section 1, modulo the convenient mance of viewing full occultations as induced subgraphs of a fixed graph $G$ with their “(S, L) partition” given, rather than independently defined graphs.

As promised, our main result is an extension of Theorem 1.4 to a characterization of obstructions to bounded treewidth in $(c, o)$-perforated graphs for every $o \geq 1$. It turns out that Theorem 1.4 remains true for $(c, o)$-perforated graphs at the cost of “relaxing the invadedness of full occultations.” To be more precise, given a graph $G$ and integers $s \geq 0$ and $o \geq 1$, we say an ordered $s$-asterism $a$ in $G$ is $o$-invaded if for every $i \in [s]$:

- (OI) $\pi_a(i)$ has at least one neighbor in every closed $a^{i-1}$-piece of length at least $o$. 

Theorem 3.1. Let \( s \geq 0 \) and \( o \geq 1 \) be integers and let \( G \) be a graph. Then the following hold.

(a) Let \( g \geq 0 \) be an integer and let \( \sigma \) be a full \((g, s, o)\)-occultation in \( G \). Then \( \sigma^s \) is a full \((g, s, o)\)-occultation in \( G \) and \( G[V(\sigma^s)] \) has girth more than \( g + 2 \).

(b) Let \( \sigma \) be a full \((s, o)\)-occultation in \( G \). Then \( G[V(\sigma)] \) is \((2, o)\)-perforated and has treewidth at least \( s - 1 \).

Proof. We leave the proof of (a) to the reader as it is easy, and will only give a proof (b), which is almost identical to the proof of Theorem 1.6 in [6]. The assertion is trivial for \( s = 0 \). Let \( s \geq 1 \) and let \( G' = G[V(\sigma)] \). Then \( G' \) contains a subdivision of an \( s \)-occultation as a subgraph, and so by Theorem 1.6, \( G' \) has treewidth at least \( s - 1 \). Now suppose for a contradiction that there are two disjoint and anticomplete cycles \( H_1 \) and \( H_2 \) in \( G' \), each of length at least \( o + 2 \). It follows that for each \( i \in \{1, 2\} \), both \( H_1 \cap S_i \) and \( H_1 \cap L_o \) are non-empty. Let \( i \in [s] \) be maximum with \( \pi_s(i) \in H_1 \cup H_2 \), and without loss of generality, assume that \( \pi_s(i) \in H_2 \). Let \( P \) be a connected component of \( H_1[V(H_1) \cap V(L_o)] \). Then we may write \( \partial P = \{x, y\} \) such that for some choice of \( j, k \in [i - 1] \), \( x \) is adjacent \( \pi_s(j) \) in \( G \) and \( v \) is adjacent \( \pi_s(k) \) in \( G \). It follows that either \( P \) contains the interior of minimal \( \sigma^{i-1} \)-route, that is, \( P \) contains an open \( \sigma^{i-1} \)-piece \( P' \), or \( j = k \) and \( P \) is a closed \( \sigma^{i-1} \)-piece. In the former case, since \( \sigma \) is interrupted, by (INT), \( \pi_s(i) \in V(H_2) \) has a neighbor in \( P' \subseteq P \subseteq H_1 \). But this violates the assumption that \( H_1 \) and \( H_2 \) are anticomplete in \( G \). Also, in the latter case, we have \( H_1 = \pi_s(j)-u-P-v-\pi_s(j) \). Since \( H_1 \) has length at least \( o + 2 \), it follows \( P \) has length at least \( o \). More precisely, \( P \) is a closed \( \sigma^{i-1} \)-piece of length at least \( o \). But then since \( \sigma \) is \( o \)-invaded, by (OI), \( \pi_s(i) \in V(H_2) \) has a neighbor in \( P \subseteq H_1 \), again a contradiction with \( H_1 \) and \( H_2 \) being anticomplete. This completes the proof of Theorem 3.1.

We can now state the main result of this paper:

Theorem 3.2. For all integers \( c, o, t \geq 1 \) and \( s \geq 0 \), there exists an integer \( \tau = \tau(c, o, s, t) \geq 1 \) such that for every \((c, o)\)-perforated graph \( G \) of treewidth more than \( \tau \), either \( G \) contains \( K_t \), or \( G \) contains \( K_{t,t} \), or there is a full \((s, o)\)-occultation in \( G \).

In view of Theorem 3.1(b), Theorem 3.2 provides a grid-like theorem for the class of \((c, o)\)-perforated graphs for all \( c, o \geq 1 \). Moreover, to make sure that all three outcomes of Theorem 3.2 are necessary, we may combine Theorem 3.2 and Theorem 3.1(a) which immediately yields the following more “efficient” version of Theorem 3.2:

Corollary 3.3. For all integers \( c, o, t \geq 1 \) and \( g, s \geq 0 \), there exists an integer \( \tau = \tau(c, g, o, s, t) \geq 1 \) such that for every \((c, o)\)-perforated graph \( G \) of treewidth more than \( \tau \), either \( G \) contains \( K_t \), or \( G \) contains \( K_{t,t} \), or there is a full \((s, o)\)-occultation \( \sigma \) in \( G \) such that \( G[V(\sigma)] \) has girth more than \( g + 2 \).

4. The cherry on top

Recall that every full occultation is both ample and interrupted. Our goal in this section is to show that in perforated graphs, a qualitative converse holds, too:

Theorem 4.1. Let \( c, o \geq 1 \) and \( s \geq 0 \) be integers. Let \( G \) be a \((c, o)\)-perforated graph. Assume that there exists a \( d \)-ample, interrupted ordered \( s^d \)-asterism \( \alpha \) in \( G \) for some integer \( d \geq 3 \). Then there exists a full \((s, o)\)-occultation \( \sigma \) in \( G \) with \( S_o \subseteq S_a \) and \( L_o \subseteq L_a \).

The proof of Theorem 4.1 calls for a few definitions and lemmas. Let \( G \) be a graph and let \( x \in V(G) \). Let \( \alpha' \) be an (ordered) asterism in \( G \) with \( V(\alpha') \subseteq V(G) \setminus \{x\} \). We say \( x \) is a cherry on top of \( \alpha' \) in \( G \) if:
(CH1) \( x \) is anticomplete in \( G \) to \( \partial L_\alpha \); and

(\text{CH2}) \( x \) has a neighbor in every open \( \alpha' \)-piece. In particular, \( x \) has a neighbor in \( L_\alpha \).

Now, let \( G \) be graph, let \( x \in V(G) \), let \( s' \geq 0 \) be an integer and let \( \alpha' \) be an ordered \( s' \)-asterism in \( G \) with \( V(\alpha') \subseteq V(G) \setminus \{ x \} \) such that \( x \) is a cherry on top of \( \alpha' \) in \( G \). Then by (CH1) and (CH2), \( \text{Cher}(\alpha', x) = (S_\alpha' \cup \{ x \}, L_\alpha) \) is an ordered \((s'+1)\)-asterism in \( G \) with \( \pi_{\text{Cher}(\alpha', x)}(s'+1) = x \) and \( \pi_{\text{Cher}(\alpha', x)}(i) = \pi_{\alpha'}(i) \) for all \( i \in [s'] \). In addition, by (CH2), \( \text{Cher}(\alpha', x) \) is interrupted if and only if \( \alpha' \) is interrupted.

One may note that the notion of a “cherry on top” arises naturally from viewing interrupted ordered asterisms as ordered asterisms which can be constructed by “successively adding cherries on top.” Said more carefully, it is straightforward to observe that given a graph \( G \) and an integer \( s \geq 0 \), an ordered \( s \)-asterism \( \alpha \) in \( G \) is interrupted if and only if for every \( i \in [s] \), \( \pi_{\alpha}(i) \) is a cherry on top of \( \alpha^{-1} \) in \( G \).

Accordingly, our first lemma, which we will use both here and in Section 6, provides a tool for growing interrupted “sub-asterisms” of a given asterism by adding one cherry on top at a time. It roughly says the following: let \( G \) be a graph, let \( \alpha \) be an asterism in \( G \) which is “ample enough” and let \( x \in S_\alpha \). Let \( S' \subseteq S_\alpha \setminus \{ x \} \) such that \( x \) is a cherry on top of \( \alpha|S' = (S', L_\alpha) \) in \( G \). Then the same is also inherited by an “optimally” chosen subpath \( L' \subseteq L_\alpha \), that is, \( x \) is a cherry on top of the asterism \((S', L') \) in \( G \). To make this notion of “optimality” precise, let \( G \) be a graph, let \( \alpha \) be an asterism in \( G \) which may or may not be ordered, let \( x \in S_\alpha \) and let \( s' \geq 0 \) be an integer. By an \((\alpha, x, s')\)-candidate in \( G \) we mean an interrupted ordered \( s' \)-asterism \( \alpha' \) in \( G \) with \( S_{\alpha'} \subseteq S_\alpha \setminus \{ x \} \) and \( L_{\alpha'} \subseteq L_\alpha \), such that:

\[ \text{(CA)} \] for every interrupted ordered \( s' \)-asterism \( \alpha'' \) in \( G \) with \( S_{\alpha''} = S_{\alpha'}, \pi_{\alpha''} = \pi_{\alpha'} \) and \( L_{\alpha''} \subseteq L_{\alpha'} \subseteq L_\alpha \), there exists \( i \in [s'-1] \) such that \( \pi_{\alpha''}(i) = \pi_{\alpha'}(i) \) has a neighbor in \( L_{\alpha''} \setminus L_{\alpha'} \).

In particular, we have \( s' \geq 2 \).

We deduce that:

Lemma 4.2. Let \( s \geq 1 \) be an integer. Let \( G \) be a graph and let \( \alpha \) be a \( d \)-ample \( s \)-asterism in \( G \) for some integer \( d \geq 2 \). Let \( x \in S_\alpha \) and let \( \alpha' \) be an \((\alpha, x, s-1)\)-candidate in \( G \). Assume that \( x \) is a cherry on top of \( \alpha|S'_\alpha = (S', L_\alpha) \) in \( G \). Then \( x \) is a cherry on top of \( \alpha' \) in \( G \). Consequently, \( \text{Cher}(\alpha', x) \) is a \( d \)-ample, interrupted ordered \( s \)-asterism in \( G \) with \( S_{\text{Cher}(\alpha', x)} \subseteq S_\alpha \) and \( L_{\text{Cher}(\alpha', x)} \subseteq L_\alpha \).

Proof. We need to show that \( \alpha' \) and \( x \) satisfy (CH1) and (CH2). Let us begin with the following:

(1) \( \text{Let } u \in \partial L_{\alpha'} \setminus \partial L_\alpha. \text{ Then the unique neighbor of } u \text{ in } L_\alpha \setminus L_{\alpha'} \text{ has a neighbor in } \pi_{\alpha'([s-2])}. \)

Suppose not. Let \( u' \) be the unique neighbor of \( u \) in \( L_\alpha \setminus L_{\alpha'} \). Then \( u' \) is anticomplete to \( \pi_{\alpha'([s-2])} \). Since \( u \) is not an end of \( L_\alpha \) and \( \alpha' \) is an \((\alpha, x, s-1)\)-candidate in \( G \), it follows from (CA) that \( S_{\alpha'} \neq \emptyset \) (indeed, we have \( s \geq 3 \)). Also, \( u' \) is adjacent to \( x' = \pi_{\alpha'}(s-1) \), as otherwise \( \alpha'' = (S_{\alpha'}, L_{\alpha'} \cup \{ u' \}) \) is an interrupted ordered \((s-1)\)-asterism in \( G \) violating (CA). Let \( u'' \) be the end of \( L_\alpha \) for which \( u-L_{\alpha'}-u'' \) contains \( u' \). Since \( x' \) is adjacent to \( u' \) and \( x' \) is not adjacent to \( u'' \), traversing \( u'-L_{\alpha'}-u'' \) from \( u' \) to \( u'' \), we may choose the first vertex \( w \) which is not adjacent to \( x' \). It follows that \( u' \neq w \) but \( u'' \) and \( w \) might be the same. Let \( u'' \) be the unique neighbor of \( w \) in \( u'-L_{\alpha'}-w \) (so \( u' \) and \( u'' \) might be the same). Since \( \alpha \) is \( d \)-ample and \( x' \) is complete to \( u'-L_{\alpha'}-w' \), it follows that \( \pi_{\alpha'([s-2])} \) is anticomplete to \( u'-L_{\alpha'}-w \). Now, let \( v \) be the end of \( L_\alpha \) distinct from \( u \) and let \( L'' = v-L_{\alpha'} \). Then \( \alpha'' = (S_{\alpha'}, L'') \) is an interrupted ordered \((s-1)\)-asterism in \( G \) with \( S_{\alpha''} = S_{\alpha'}, \pi_{\alpha''} = \pi_{\alpha'}, \) and \( L_{\alpha''} \subseteq L'' = L_{\alpha'} \subseteq L_\alpha \), for which \( \pi_{\alpha'([s-2])} = \pi_{\alpha'([s-2])} \) is anticomplete to \( L'' \setminus L_{\alpha'} = u'-L_{\alpha'}-w \). But then by (CA), \( \alpha' \) is not an \((\alpha, x, s-1)\)-candidate in \( G \), a contradiction. This proves (1).

From (1) and the fact that \( \alpha \) is \( d \)-ample, it follows that \( x \) is anticomplete to the ends of \( L_{\alpha'} \), and so \( \alpha' \) and \( x \) satisfy (CH1). Also, we claim that:
(2) Let $P$ be an open $a'$-piece. Then $x$ has a neighbor in $P$.

First, assume that $P$ is an internal open $a'$-piece. Then $P$ is an open $a|S_{a'}$-piece. Since $x$ is a cherry on top of $a|S_{a'}$ in $G$, it follows from (CH2) that $x$ has a neighbor in $P$, as desired. Next, assume that $P$ is an external $a'$-piece. Then $P$ and $L_{a'}$ share at least one end, say $u$. By (1), either $u$ is an end of $L_{a'}$, or the unique neighbor $u'$ of $u$ in $L_{a} \setminus L_{a'}$ is adjacent to $\pi_{a'}(i)$ for some $i \in [s - 2]$. In the former case, $P$ is an external $a|S_{a'}$-piece, and so $P$ is an open $a|S_{a'}$-piece. Again, since $x$ is a cherry on top of $a|S_{a'}$ in $G$, it follows from (CH2) that $x$ has a neighbor in $P$. In the latter case, traversing $L_{a'}$ starting at $u$, let $u''$ be the first vertex with a neighbor in $S_{a'}$. Since $a'$ is interrupted, it follows that $u''$ is a neighbor of $\pi_{a'}(s - 1)$, and so there exists an $a|S_{a'}$-route $R$ from $\pi_{a'}(s - 1)$ to $\pi_{a'}(i)$ such that $P = R^* \setminus \{u'\}$. Note that since $a$ is $d$-ample, the ends of $R^*$ have no common neighbor in $S_{a'}$, and so $R^*$ is an open $a|S_{a'}$-piece. Therefore, since $x$ is a cherry on top of $a|S_{a'}$ in $G$, it follows from (CH2) that $x$ has a neighbor in $R^*$. On the other hand, since $x'' \in S_a \setminus \{x\}$ is adjacent to $u'$ and $a$ is $d$-ample, it follows that $x$ is not adjacent to $u'$. But now $x$ has a neighbor in $P$. This proves (2).

By (2), $a'$ and $x$ satisfy (CH2). This completes the proof of Lemma 4.2. \hfill \blacksquare

We also need the following, which is an application of Lemma 4.2:

**Lemma 4.3.** Let $o \geq 1$ and $v, v', s$ be integers such that $v > v' \geq s - 1 \geq 0$. Let $G$ be a graph and let $a$ be a $d$-ample, interrupted ordered $v$-asterism in $G$ for some integer $d \geq 2$. Assume that $\pi_{a}(v)$ has a neighbor in every closed $a^{v'}$-piece of length at least $o$. Assume also that there exists a full $(s - 1, o)$-occlusion $o'$ in $G$ with $S_{o'} \subseteq S_{a^{v'}}$ and $L_{o'} \subseteq L_{a}$. Then there exists a full $(s, o)$-occlusion $o$ in $G$ with $S_{o} \subseteq S_{a}$ and $L_{o} \subseteq L_{a}$.

**Proof.** We write $x = \pi_{a}(v)$. Choose a full $(s - 1, o)$-occlusion $o'$ in $G$ with $S_{o'} \subseteq S_{a^{v'}}$ and $L_{o'} \subseteq L_{a}$, such that $L_{o'}$ is maximal with respect to inclusion. In particular, $o'$ is ample, interrupted and $o$-invaded with $S_{o'} \subseteq S_{a^{v'}} \subseteq S_{a} \setminus \{x\}$. We further deduce that:

(3) $o'$ is an $(a, x, s - 1)$-candidate in $G$ and $x$ is a cherry on top of $a|S_{a'}$ in $G$.

Note that from the maximality of $L_{o'}$, it follows immediately that $a$, $o'$ and $x$ satisfy (CA). Therefore, $o'$ is an $(a, x, s - 1)$-candidate in $G$. It remains to show that $x$ is a cherry on top of $a|S_{a'}$. To that end, we need to argue that $a|S_{o'}$ and $x$ satisfy (CH1) and (CH2). Observe that (CH1) follows immediately from the fact that $L_{a|S_{o'}} = L_{a}$. For (CH2), let $P$ be an open $a|S_{a'}$-piece. Since $S_{o'} \subseteq S_{a^{v'}} \subseteq S_{a^{v-1}}$, it follows that $P$ contains an open $a^{v-1}$-piece $P'$. But now since $a$ is interrupted, it satisfies (INT) for $i = v$, that is, $x = \pi_{a}(v)$ has a neighbor in the open $a^{v-1}$-piece $P'$, and so $x$ has a neighbor in $P$. This proves (3).

In view of (3), we can apply Lemma 4.2 to $a$, $o'$ and $x$, and deduce that $o = \text{Cher}(o', x)$ is a $d$-ample, interrupted ordered $s$-asterism in $G$ with $S_{o} = S_{o'} \cup \{x\} \subseteq S_{a}$ and $L_{o} \subseteq L_{a}$.

We also have:

(4) $o$ is $o$-invaded.

We need to prove that $o$ satisfies (OI) for every $i \in [s]$. This is immediate for $i \in [s - 1]$ as $o'$ is $o$-invaded. For $i = s$, let $P$ be a closed $a^{s-1}$-piece of length at least $o$. Our goal is to show that $\pi_{a}(s) = x$ has a neighbor in $P$. Since $S_{a^{s-1}} \subseteq S_{a^{v'}} \subseteq S_{a^{v-1}}$, it follows that either $P$ is a closed $a^{v'}$-piece, or $P$ contains an open $a^{v'}$-piece, which in turn implies that $P$ contains an open $a^{v-1}$-piece $P'$. In the former case, $\pi_{a}(s) = x$ has a neighbor in $P$ due to the assumption of Lemma 4.3 that $\pi_{a}(v) = x$ has a neighbor in every closed $a^{v'}$-piece of length at least $o$. In the latter case, since $a$ is interrupted, $a$ satisfies (INT) for $i = v$. In particular, $x = \pi_{a}(v)$ has a neighbor in the open $a^{v-1}$-piece $P'$, and so $x$ has a neighbor in $P$. This proves (4).
In conclusion, we have shown that \( o \) is a \( d \)-ample, interrupted and \( o \)-invaded ordered \( s \)-asterism in \( G \) with \( S_o \subseteq S_a \) and \( L_o \subseteq L_a \). Hence, \( o \) is a full \( (s,o) \)-occultation in \( G \) with \( S_o \subseteq S_a \) and \( L_o \subseteq L_a \). This completes the proof of Lemma 4.3. \( \blacksquare \)

We can now prove the main result of this section:

**Proof of Theorem 4.1.** We proceed by induction on \( c + s \geq 1 \). The result is immediate for \( s \in \{0, 1\} \) as in this case \( a \) is a full \( (s,o) \)-occultation in \( G \). So we may assume that \( s \geq 2 \), which in turn implies that \( c + s \geq 3 \).

Let \( G \) be a \((c,o)\)-perforated graph, let \( a \) be a \( d \)-ample, interrupted ordered \( s^c \)-asterism in \( G \) for some integer \( d \geq 3 \), and suppose for a contradiction that there is no full \((s,o)\)-occultation \( o \) in \( G \) with \( S_o \subseteq S_a \) and \( L_o \subseteq L_a \). Write \( v = s^c \), \( v' = (s - 1)^c \) and \( x = \pi_a(v) \). It follows that \( v > v' \geq 1 \). We deduce that:

**5** There exists a closed \( a^{v'} \)-piece \( P \) of length at least \( o \) such that \( x \) is anticomplete to \( P \).

Suppose not. Then \( x = \pi_a(v) \) has a neighbor in every closed \( a^{v'} \)-piece \( P \) of length at least \( o \). Note that \( a^{v'} \) is an ordered \( v' \)-asterism in \( G \). Also, \( a^{v'} \) is both \( d \)-ample and interrupted, because \( a \) is. Consequently, by the induction hypothesis, there is a full \((s - 1, o)\)-occultation \( o' \) in \( G \) with \( S_o' \subseteq S_{a^{v'}} \) and \( L_o' \subseteq L_{a^{v'}} = L_a \). But now by Lemma 4.3, there exists a full \((s,o)\)-occultation \( o \) in \( G \) with \( S_o \subseteq S_a \) and \( L_o \subseteq L_a \), a contradiction. This proves (5).

Henceforth, let \( P \) be as in (5). Then there exists a vertex \( z \in S_{a^{v'}} = \pi_a([v']) \) which is adjacent to both ends of \( P \). It follows \( H = P \cup \{z\} \) is a cycle in \( G \) of length at least \( o + 2 \). As a result, we have \( c \geq 2 \). Moreover, we claim that:

**6** \( S_a \setminus \{z\} \) is anticomplete to \( P \), and so to \( H \).

By (5), \( x \) is anticomplete to \( P \). Suppose for a contradiction that \( x' \in S_a \setminus \{x, z\} \) has a neighbor in \( P \). Then \( P \) contains the interior of an \( a \)-route \( R \) from \( x' \) to \( z \). Since \( x', z \in S_a \setminus \{x\} = S_{a^{v-1}} \), it follows that \( R \) is an \( a^{v-1} \)-route, and so \( R^* \) is an open \( a^{v-1} \)-piece. Therefore, since \( a \) is interrupted, by (INT) for \( i = v \), \( x = \pi_a(v) \) has a neighbor in the interior of the open \( a^{v-1} \)-piece \( R^* \). But then \( x \) has a neighbor in \( P \), a contradiction. This proves (6).

Now, since \( c, s \geq 2 \), we have:

\[
v - v' = s^c - (s - 1)^c = \sum_{i=1}^{c} s^{c-i}(s - 1)^{i-1} \geq s^{c-1} + s^{c-2}(s - 1);
\]

which in turn implies that:

\[
v - (v' + 1) \geq s^{c-1} + s^{c-2}(s - 1) - 1 \geq s^{c-1} - s^{c-2} - 1 > 1.
\]

In particular, for \( S = \pi_a([v] \setminus [v - s^{c-1}]) \), we have \( S \subseteq \pi_a([v] \setminus [v' + 1]) \) with \( |S| = s^{c-1} > 1 \) and \( x = \pi_a(v) \in S \). Let \( y = \pi_a(v' + 1) \). It follows that \( y, z \notin S \). By (6), \( S \) is anticomplete to \( H \).

Next, note that since both \( y, z \) have neighbors in \( L_a \), there exists an \( a \)-route \( R \) from \( y \) to \( z \). Let \( Q = R^* \). Since \( a \) is \( d \)-ample, it follows that \( Q^* \neq \emptyset \). Also, by (6), \( P \) and \( Q \) share at most one vertex (which would be a common end of \( P \) and \( Q \)). Let \( \partial Q = \{u, v\} \) such that \( y \) and \( z \) are adjacent to \( u \) and \( v \), respectively. Let \( L = Q \setminus (N_Q[u] \cup N_Q[v]) \). Then we have:

**7** \( L \) is anticomplete to \( H \). Also, every vertex in \( S \) has a neighbor in \( L^* \), and \( S \) is anticomplete to \( \partial L \). In particular, we have \( L \neq \emptyset \).

The first assertion is immediate from the definition of \( L \). For the second assertion, let \( x' \in S \).

Then we have \( x' = \pi_a(i) \) for some \( i \in [v] \setminus [v' + 1] \). Since \( R \) is an \( a \)-route from \( y \) to \( z \), it follows that \( R \) is an \( a^{v-1} \)-route, and so \( Q \) contains an open \( a^{v-1} \)-piece \( Q' \). Therefore, by the assumption that \( a \) is interrupted, \( x' \) has a neighbor in \( Q' \subseteq Q \). On the other hand, note that \( y, z \in S_a \setminus \{x'\} \),
y is adjacent to u and z is adjacent to v. Therefore, since a is d-ample, it follows that x' has a neighbor in L′ and S is anticomplete to the ends of L. This proves (7).

We are almost done. Let G′ = G[S ∪ L]. From (7), we concludes that α′ = (S, L) is an ordered \( s^{e-1} \)-asterism in G′ with \( π_{α}(i) = π_{α}(v-s^{e-1}+i) \) for every \( i \in [s^{e-1}] \). Also, α′ is both interrupted and d-ample, as so is α. Recall the assumption that there is no full (s, o)-occultation \( σ \) in G with \( S_0 \subseteq S_0 \) and \( L_0 \subseteq L_0 \). It follows that there is no full (s, o)-occultation \( σ \) in G′ with \( S_0 \subseteq S_0 ′ \) and \( L_0 \subseteq L_0 ′ \). Hence, by the induction hypothesis applied to G′ and α′, G′ contains \( c-1 \) pairwise disjoint and anticomplete cycles H_1, . . . , H_{c-1}, each of length at least \( o+2 \). On the other hand, by (6) and (7), \( V(G′) \) is anticomplete to H in G. But now \( H, H_1, . . . , H_{c-1} \) is a collection of \( c \) pairwise disjoint and anticomplete cycles in G, each of length at least \( o+2 \), a contradiction with the assumption that G is \((c, o)\)-perforated. This completes the proof of Theorem 4.1.  

5. Bundles and Constellations

Let G be a graph and \( l \geq 1 \) be an integer. By an l-polypath in G we mean a set L of l pairwise disjoint paths in G. Given an l-polypath L in G, we say L is plain if every two distinct paths \( L, L′ \in L \) are anticomplete in G. Also, two polypaths L and \( L′ \) in G are said to be disentangled if \( V(L) ∩ V(L′) = ∅ \). For an integer \( s \geq 0 \), an \((s, l)\)-bundle in G is a pair \( b = (S_b, \mathcal{L}_b) \) where \( S_b \subseteq V(G) \) with \( |S_b| = s \) and \( \mathcal{L}_b \) is an l-polypath in G (note that \( S_b \) and \( V(\mathcal{L}_b) \) are not necessarily disjoint.) By an \((s, l)\)-bundle in G, we mean an \((s', l)\)-bundle in G for some integer \( 0 \leq s' \leq s \). Given an \((s, l)\)-bundle b in G, we write \( V(b) = S_b ∪ V(\mathcal{L}_b) \), and we say that b is plain if the l-polypath \( \mathcal{L}_b \) is plain. Also, two bundles b and \( b′ \) in a graph G are said to be disentangled if \( V(b) ∩ V(b′) = ∅ \).

The main result of this section, Theorem 5.1 below, is a Ramsey-type result concerning pairwise disentangled plain bundles in perforated graphs. This involves a specific type of bundles which we need to define separately. Given a graph G and integers \( s \geq 0 \) and \( l \geq 1 \), an \((s, l)\)-constellation in G is an \((s, l)\)-bundle c = \((S_c, \mathcal{L}_c)\) in G such that \( S_c \) is a stable set (of cardinality \( s \)) in \( G \setminus V(\mathcal{L}_c) \), and for every \( s \in S_c \) has a neighbor in every path \( L \in \mathcal{L}_c \), \( s \) has a neighbor in \( L \) (which may belong to \( ∂L \); in other words, \( (S_c, L) \) is not necessarily an s-asterism in G.)

**Theorem 5.1.** For all integers \( a, b, c, h, l, o, s, t \) \( \geq 1 \), there exist integers \( Θ = Θ(a, b, c, h, l, o, s, t) \geq 1 \) and \( θ = θ(a, b, c, h, l, o, s, t) \geq 1 \) with the following property. Let G be a \((c, o)\)-perforated graph and let \( \mathcal{I} \) be a collection of \( Θ \) pairwise disentangled plain \((≤ b, θ)\)-bundles in G. Then one of the following holds.

(a) G contains either \( K_1 \) or \( K_{1,1} \).
(b) There exists a plain \((s, l)\)-constellation in G.
(c) There exists \( \mathfrak{A} \subseteq \mathcal{I} \) with \( |\mathfrak{A}| = a \) as well as \( H_b \subseteq L_b \) with \( |H_b| = h \) for each \( b \in \mathfrak{A} \), such that for all distinct \( b, b′ \in \mathfrak{A} \), \( S_b ∪ V(H_b) \) is anticomplete to \( S_{b′} ∪ V(H_{b′}) \) in G.

Our way towards the proof of Theorem 5.1 passes through an assortment of definitions and lemmas, often of independent interest and even with applications in subsequent sections. We begin with two lemmas which capture our main use of Theorems 2.1 and 2.2.

**Lemma 5.2.** For all integers \( b, f, g, m, n, t \) \( \geq 1 \) and \( s \geq 0 \), there exists an integer \( β = β(b, f, g, m, n, s, t) \geq 1 \) with the following property. Let G be a graph and let \( \mathcal{B} \) be a collection of \( β \) pairwise disentangled \((≤ b, 2b(g-1) + f)\)-bundles in G. Then one of the following holds.

(a) G contains either \( K_1 \) or \( K_{1,1} \).
(b) There exist \( \mathfrak{M} \subseteq \mathcal{B} \) with \( |\mathfrak{M}| = n \) as well as \( S \subseteq \bigcup_{b \in \mathfrak{M}} S_b \) with \( |S| = s \), such that for every \( b \in \mathfrak{M} \), there exists \( G_b \subseteq L_b \) with \( |G_b| = g \) for which \( (S, G_b) \) is an \((s, g)\)-constellation in G. As a result, \( (S, \bigcup_{b \in \mathfrak{M}} G_b) \) is an \((s, gn)\)-constellation in G.
(c) There exist \( \mathfrak{M} \subseteq \mathcal{B} \) with \( |\mathfrak{M}| = m \) as well as \( F_b \subseteq L_b \) with \( |F_b| = f \) for each \( b \in \mathfrak{M} \), such that for all distinct \( b, b′ \in \mathfrak{M} \), \( S_b \) is anticomplete to \( S_{b′} ∪ V(F_{b′}) \) in G.
Proof. Let \( l = 2b(g-1) + f \) and let \( \rho = \rho(\max\{m, n + s, 2t\}, 2, 2b^2 + 2bl) \) be as in Theorem 2.1. Let
\[
\beta = \beta(b, f, g, m, n, s, t) = (b+1)\rho.
\]
Suppose that Lemma 5.2(a) and Lemma 5.2(b) do not hold. From the choice of \( \beta \), it follows that there exists \( c \in \{0, 1, \ldots, b\} \) as well as \( C \subseteq B \) with \( |C| = \rho \) such that for every \( b \in C \), we have \( |S_b| = c \). Consider the following three pairwise disjoint sets:
\[
X = \{x_i : i \in [c]\};
X' = \{x_i' : i \in [c]\};
L = \{L_1, \ldots, L_l\}.
\]
Let \( W \) be the set of all vertex-labelled 3-partite graphs with vertex set \( X \cup X' \cup L \) and 3-partition \( (X, X', L) \). So we have \( |W| = 2^{c+2cl} \leq 2^{b^2+2bl} \).

Next, let us write \( C = \{b_1, \ldots, b_p\} \), and every \( i \in [\rho] \), let \( S_{b_i} = \{x_i^1, \ldots, x_i^j\} \) and \( L_{b_i} = \{L_1, \ldots, L_l\} \). For every 2-subset \( \{i, j\} \) of \( [\rho] \) with \( i < j \), let \( W_{i,j} \) be the unique graph in \( W \) with the following specifications:
\[
(W1) \text{ For all } p, q \in [c] \text{, we have } x_p x_q' \in E(W_{i,j}) \text{ if and only if we have } x_p' x_q' \in E(G).
(W2) \text{ For all } p \in [c] \text{ and } q \in [l] \text{, we have } x_p L_q \in E(W_{i,j}) \text{ if and only if } x_p' \text{ has a neighbor in } L_q' \text{ in } G.
(W3) \text{ For all } p \in [c] \text{ and } q \in [l] \text{, we have } x_p' L_q \in E(W_{i,j}) \text{ if and only if } x_p' \text{ has a neighbor in } L_q' \text{ in } G.
\]
Now, let \( \Phi : \binom{[\rho]}{2} \rightarrow W \) be the map with \( \Phi(\{i, j\}) = W_{i,j} \) for every 2-subset \( \{i, j\} \) of \( [\rho] \) with \( i < j \). It follows that \( \Phi \) is well-defined. The choice of \( \rho \) then allows an application of Theorem 2.1, which implies that there exists \( I \subseteq [\rho] \) with \( |I| = \max\{m, n + s, 2t\} \) as well as \( W \in W \) such that for every 2-subset \( \{i, j\} \) of \( I \) with \( i < j \), we have \( \Phi(\{i, j\}) = W_{i,j} = W \). In particular, one may pick \( I_1, I_2, I_3 \subseteq I \) such that
\[
|I_1| = |J_1| = t \text{ and } \max I_1 < \min J_1;
|I_2| = s \text{, } |J_2| = n \text{ and } \max I_2 < \min J_2;
|I_3| = s \text{, } |J_3| = n \text{ and } \max J_3 < \min I_3; \text{ and}
|M| = m.
\]
We claim that:

\[
(8) \text{ The sets } \{S_{b_i} : i \in I\} \text{ are pairwise anticomplete in } G.
\]

In view of (W1), it suffices to show that \( X \) and \( X' \) are anticomplete in \( W \). Note that if \( x_p x_q' \in E(W) \) for some \( p \in [c] \), then by (W1), \( G(\{x_p : i \in I_1\}) \) is isomorphic to \( K_t \) and so Lemma 5.2(a) holds, a contradiction. It follows that, for every \( p \in [c] \), \( x_p \) and \( x_p' \) are non-adjacent in \( W \), and so by (W1), \( \{x_p' : i \in I\} \) is a stable set in \( G \). Now, assume that \( x_p x_q' \in E(W) \) for some \( p, q \in [c] \). It follows that \( p \) and \( q \) are distinct and \( \{x_p' : i \in I_1\} \) and \( \{x_q' : j \in J_1\} \) are both stable sets in \( G \). But then by (W1), \( G(\{x_p' : i \in I_1\} \cup \{x_q' : j \in J_1\}) \) is isomorphic to \( K_{t, t} \), and so Lemma 5.2(a) holds, again a contradiction. This proves (8).

\[
(9) \text{ There exists } F \subseteq [l] \text{ with } |F| = f \text{ such that } X \cup X' \text{ is anticomplete to } \{L_q : q \in F\} \text{ in } W.
\]

Suppose not. Then since \( |X| = |X'| = c \) and \( |L| = l = 2b(g-1) + f \geq 2c(g-1) + f \), counting the edges between \( X \cup X' \) and \( L \) in the graph \( W \) shows that there exists a vertex in \( X \cup X' \) which has at least \( g \) neighbors in \( L \) (in \( W \)). In other words, there exists \( p \in [c] \) and \( F' \subseteq [l] \) with \( |F'| = g \) such that one of \( x_p \) and \( x_p' \) is complete to \( \{L_q : q \in F'\} \) in \( W \). This, along with (W2) and (W3), implies that there exists \( k \in \{2, 3\} \) such that for every \( i \in I_k \), every \( j \in J_k \) and every \( q \in F' \), \( x_p \in S_b \) has a neighbor in \( L_q \). Let \( S = \{x_p' : i \in I_k\} \). Let \( N = \{b_j : j \in J_k\} \); so we have \( |N| = n \). For every \( j \in J_k \), let \( G_{b_j} = \{L_q' : q \in F' \} \subseteq \mathcal{L}_b \); so \( G_{b_j} \) is a }-polypath
in $G$. It follows that $S \subseteq \bigcup_{b \in \mathfrak{N}} S_b$, and by (8), $S$ is a stable set in $G \setminus \bigcup_{b \in \mathfrak{N}} V(G_b)$. Also, from (8) and the choice of $k$, it follows that for every $b \in \mathfrak{N}$ and every path $L \in G_b$, every vertex in $S$ has a neighbor in $L$ in $G$. Thus, $(S, G_b)$ is an $(s, g)$-constellation in $G$. But now $\mathfrak{N}, S$ and $\{G_b : b \in \mathfrak{N}\}$ satisfy (b), a contradiction. This proves (8).

To finish the proof, let $\mathfrak{N} = \{b_j : j \in M\}$; then $|\mathfrak{N}| = m$. Let $F$ be as in (9), and for every $j \in M$, define the $f$-polypath $F_{b_j} = \{L'_q : q \in F\} \subseteq L_{b_j}$. For all distinct $i, j \in M$, it follows from (8) that $S_{b_i}$ is anticomplete to $S_{b_j} \cup \partial F_{b_j}$ in $G$, and from (9), (W2) and (W3) that $S_{b_i}$ is anticomplete to $F_{b_j}$ in $G$. In conclusion, we have shown that for all distinct $i, j \in M$, $S_{b_i}$ is anticomplete to $S_{b_j} \cup V(F_{b_j})$. Hence, $\mathfrak{N}$ and $\{F_b : b \in \mathfrak{N}\}$ satisfy (c). This completes the proof of Lemma 5.2.

Lemma 5.3. For all integers $a, g \geq 1$, there exists an integer $\varphi = \varphi(a, g) \geq 1$ with the following property. Let $G$ be a graph and let $F_1, \ldots, F_a$ be a collection of a pairwise disentangled $\varphi$-polypaths in $G$. Then for every $i \in [a]$, there exists a $g$-polypath $G_i \subseteq F_i$, such that for all distinct $i, i' \in [a]$, either $V(G_i)$ is anticomplete to $V(G_{i'})$ in $G$, or for every $L \in G_i$ and every $L' \in G_{i'}$, there is an edge in $G$ with an end in $L$ and an end in $L'$.

Proof. Define $\varphi = \varphi(a, g) = \nu(a, g, 2a^2)$, where $\nu(\cdot, \cdot, \cdot)$ is as in Theorem 2.2. Consider a set $X = \{x_1, \ldots, x_a\}$, and let $\mathcal{W}$ be the set of all vertex-labeled graphs with vertex set $X$; so we have $|\mathcal{W}| \leq 2a^2$. For every $F = (L_1, \ldots, L_A) \in F_1 \times \cdots \times F_a$, define $\Phi(F)$ to be the unique graph in $\mathcal{W}$ in which for all distinct $i, i' \in [a]$, we have $x_i x_{i'} \notin E(\Phi(F))$ if and only if there is an edge in $G$ with an end in $L_i$ and an end in $L_{i'}$. Then $\Phi : F_1 \times \cdots \times F_a \to \mathcal{W}$ is a well-defined map. By the choice of $\varphi$, we can apply Theorem 2.2, and deduced that there exists $W \in \mathcal{W}$ as well as $G_i \subseteq F_i$ with $|G_i| = g \geq 1$ for each $i \in [a]$, such that for every $F \in G_i \times \cdots \times G_a$, we have $\Phi(F) = W$.

Now, let $i, i' \in [a]$ be distinct. It follows immediately that, if $x_i x_{i'} \notin E(W)$, then $V(G_i)$ is anticomplete to $V(G_{i'})$ in $G$, and if $x_i x_{i'} \in E(W)$, then for every $L \in G_i$ and every $L' \in G_{i'}$, there is an edge in $G$ with an end in $L$ and an end in $L'$. This completes the proof of Lemma 5.3.

For the next lemma, we need a few more definitions. Given a graph $G$ and an integer $a \geq 1$, an $a$-syzygy in $G$ is an ordered $a$-asterism $\pi$ in $G$ such that for some end $u$ of $L_\pi$, the following holds.

(SY) For all $i, j \in [a]$ with $i < j$, every neighbor $v_i \in L_\pi$ of $\pi(i)$ and every neighbor $v_j \in L_\pi$ of $\pi(j)$, the path in $L_\pi$ from $u$ to $v_j$ contains $v_i$ in its interior. In other words, traversing $L_\pi$ starting at $u$, all neighbors of $\pi(i)$ appear “before” all neighbors of $\pi(j)$.

See Figure 5. In particular, if $\pi$ is an $a$-syzygy in $G$, then $\pi$ is ample, and for every non-empty subset $X$ of $S_\pi$, $\pi$ restricted to $X$ is an $|X|$-syzygy in $G$.

Recall that $d$-ample asterisms were introduced in Section 3 as an extension of ample asterisms. Here is another notion extending ample asterisms, but the other way around. For an integer $d \geq 0$ and an (ordered) asterism $\alpha$ in a graph $G$, we say $\alpha$ is $d$-meager if every vertex in $L_\alpha$ has
at most \(d\) neighbors in \(S_a\). It follows that \(a\) is 0-meager if and only if \(S_a = \emptyset\) and 1-meager if and only if \(a\) is ample.

We also use the following folklore fact which is a direct consequence of interval graphs being perfect (we omit further details).

**Lemma 5.4** (Berge [4]). Let \(a, b \geq 0\) be integers and let \(G\) be an interval graph on \(ab\) vertices. Then \(G\) contains either a stable set of cardinality \(a\) or a clique of cardinality \(b\).

Here is our next lemma:

**Lemma 5.5.** Let \(a, l \geq 1\) and \(d, s \geq 0\) be integers and let \(G\) be a graph. Assume that there exists a \(d\)-meager (ordered) \((a^{l-1}(s + d(l - 1)))\)-asterism \(g\) in \(G\). Then one of the following holds.

(a) There exists an \(a\)-syzygy \(s\) in \(G\) with \(S_s \subseteq S_g\) and \(L_s \subseteq L_g\).

(b) There exists a plain \((s, l)\)-constellation \(c\) in \(G\) such that \(S_c \subseteq S_g\) and \(L \subseteq L_g^*\) for every \(L \in L_c\).

**Proof.** For fixed \(a, d, s\), we proceed by induction on \(l\). Note that if \(l = 1\), then \((S_g, \{L_g^*\})\) is a plain \((s, 1)\)-constellation in \(G\) satisfying Lemma 5.5(b). Thus, we may assume that \(l \geq 2\).

Let \(\partial L_g = \{u_1, u_2\}\). For every vertex \(x \in S_g\), traversing \(L_g\) from \(u_1\) to \(u_2\), let \(v_x\) and \(w_x\) be the first and the last neighbor of \(x\) in \(L_g\), and let \(P_x\) be the unique path in \(L_g\) with ends \(v_x, w_x\).

Define \(G\) to be the graph with vertex set \(S_g\) such that for distinct \(x, y \in S_g\), we have \(xy \in E(G)\) if and only if \(P_x \cap P_y \neq \emptyset\). It is readily seen that \(G\) is an interval graph on \(a^{l-1}(s + d(l - 1))\) vertices. Thus, by Lemma 5.4, \(G\) contains either a stable set \(A\) of cardinality \(a\) or a clique \(B\) of cardinality

\[a^{l-2}(s + d(l - 1)) = a^{l-2}(s + d(l - 2)) + da^{l-2} \geq a^{l-2}(s + d(l - 2)) + d.
\]

In the former case, we may write \(A = \{x_1, \ldots, x_a\}\) such that, for all distinct \(i, j \in [a]\), the path in \(L_g\) from \(u_1\) to \(v_{x_i}\), contains \(v_{x_j}\) if and only if \(i < j\). But then \(s = (A, L_g)\) is an ordered \(a\)-asterism in \(G\) with \(\pi_s(i) = x_i\) for every \(i \in [a]\), and \(s\) together with the end \(u_1\) of \(L_g = L_g^*\) satisfy (SY). In other words, \(s\) is an \(a\)-syzygy in \(G\) with \(S_s \subseteq S_g\) and \(L_s \subseteq L_g\), and so 5.5(a) holds.

Now, assume that \(G\) contains a clique \(B\) of cardinality at least \(a^{l-2}(s + d(l - 2)) + d\). It follows that there exists a vertex \(u \in L_g^*\) such that for every \(x \in B\), we have \(u \in P_x\). Let \(L_i = u \cdot I_g \cup u\) for \(i \in \{1, 2\}\). Since \(g\) is \(d\)-meager, it follows that \(|N_{B'}(u)| \leq d\), and so there exists \(B' \subseteq B\) with \(|B'| = a^{l-2}(s + d(l - 2))\) such that for every \(i \in \{1, 2\}\), every vertex in \(B'\) has a neighbor in \(L_i^*\) and \(B'\) is anticomplete to \(\partial L_i\). It follows that, for every \(i \in \{1, 2\}\), \(g_i = (B', L_i)\) is an \((a^{l-2}(s + d(l - 2)))\)-asterism in \(G\) which is \(d\)-meager, as so is \(g\). From the induction hypothesis applied to \(g_1\), we deduce that either here exists an \(a\)-syzygy \(s\) in \(G\) with \(S_s \subseteq S_{g_1} = B' \subseteq S_g\) and \(L_s \subseteq L_{g_1} = L_1 \subseteq L_g\), or there exists a plain \((s, l - 1)\)-constellation \(c_1\) in \(G\) such that \(S_{c_1} \subseteq S_{g_1} = B' \subseteq S_g\) and \(L \subseteq L_{g_1}^* \subseteq L_1^* \subseteq L_g^*\) for every \(L \in L_c\). In the former case, Lemma 5.5(a) holds, as required. In the latter case, \(c = (S_c, L_c \cup \{L_1^*\})\) is a plain \((s, l)\)-constellation in \(G\) such that \(S_c \subseteq S_g\) and \(L \subseteq L_{g_1}^* \cup L_1^* = L_g^*\) for every \(L \in L_c\), and so Lemma 5.5(b) holds. This completes the proof of Lemma 5.5. \(\blacksquare\)

We need one more lemma, an application of Lemma 5.5, which in turn calls for one more definition. Let \(G\) be a graph and let \(g \geq 1\) be an integer. A \(g\)-gemini in \(G\) is a pair \((g_1, g_2)\) of ordered \(g\)-asterisms in \(G\) with the following specifications.

**G1** We have \(V(g_1) \cap V(g_2) = S_{g_1} \cap S_{g_2}\).

**G2** \(V(g_1) \setminus V(g_2)\) is anticomplete to \(V(g_2) \setminus V(g_1)\).

**G3** There exists a plain \(g\)-polypath \(Q = \{Q_1, \ldots, Q_g\}\) in \(G \setminus (L_{g_1} \cup L_{g_2})\), such that for every \(i \in [g]\):

- \((g_1)_i = \{\pi_{g_1}(i), \pi_{g_2}(i)\}\); and
- \((g_2)_i \setminus \{\pi_{g_1}(i)\}\) is anticomplete to \(L_{g_2}\) and \(Q_i \setminus \{\pi_{g_2}(i)\}\) is anticomplete to \(L_{g_1}\).

In particular, for every \(x \in S_{g_1} \cap S_{g_2}\), we have \(\pi_{g_1}^{-1}(x) = \pi_{g_2}^{-1}(x)\).
it follows that

Hence, $H$ satisfies $(G3)$. For every $j$ with the following property. Let $\pi_l(i) = x_j$ and $\pi_{g_2}(i) = y_j$ for each $i \in [4]$.

The paths $Q_1, \ldots, Q_4$ are depicted using dashed lines to mean they are of arbitrary (possibly zero) length.

See Figure 6. It follows that if $(g_1, g_2)$ is a $g$-gemini in $G$, then for every non-empty subset $J$ of $[g]$, $(g_1)_{\pi_l(J)}, g_2(\pi_{g_2}(J))$ is a $|J|$-gemini in $G$.

The following shows that a perforated graph containing a large gemini must also contain a large plain constellation.

Lemma 5.6. For all integers $c, l, o, s \geq 1$ and $d \geq 0$, there exists an integer $\gamma = \gamma(c, d, l, o, s) \geq 1$ with the following property. Let $G$ be a $(c, o)$-perforated graph. Assume that there exists a $\gamma$-gemini $(g_1, g_2)$ in $G$ where both $g_1$ and $g_2$ are $d$-meager. Then there exists a plain $(s, l)$-constellation in $G$.

Proof. Let $a = (4co)^{(l-1)}(s + d(l - 1)) \geq 1$ and let

$$\gamma = \gamma(c, d, l, o, s) = a^{(l-1)}(s + d(l - 1)) \geq 1.$$ 

Let $(g_1, g_2)$ be a $\gamma$-gemini in $G$. Suppose for a contradiction that there is no plain $(s, l)$-constellation in $G$. Therefore, applying Lemma 5.5 to the $d$-meager ordered $\gamma$-asterism $g_1$, it follows that there exists an $u$-syzygy $s$ in $G$ with $S_s \subseteq S_{g_1}$ and $L_s \subseteq L_{g_1}$. Let $S_2 = \pi_{g_2}(\pi_{g_1}^{-1}(S_s))$. Then we have $S_2 \subseteq S_{g_2}$ with $|S_2| = a$. Also, note that the ordered $u$-asterism $g_2|S_2$ is $d$-meager, because $g_2$ is. So another application of Lemma 5.5, this time to $g_2|S_2$, implies that there exists a $4co$-syzygy $a_2$ in $G$ with $S_{a_2} \subseteq S_{g_2}|S_2 = S_2 \subseteq S_{g_2}$ and $L_{a_2} \subseteq L_{g_2}|S_2 = L_{g_2}$. Let $S_1 = \pi_{g_1}(\pi_{g_2}^{-1}(S_{a_2})) \subseteq S_{g_1}$ and let $a_1 = s|S_1$. Then $a_1$ is a $4co$-syzygy in $G$ with $S_{a_1} = S_1 \subseteq S_{g_1}$ and $S_{a_1} = L_s \subseteq L_{g_1}$.

To sum up, we have shown that $(a_1, a_2)$ is a $4co$-gemini in $G$ such that for every $i \in \{1, 2\}$, $a_i$ is a $4co$-syzygy in $G$ with $S_{a_i} \subseteq S_{g_i}$ and $L_{a_i} \subseteq L_{g_i}$. Let $J = \{2jo : j \in [2c]\}$, and for every $i \in \{1, 2\}$, let $s_i = a_i|\pi_{a_i}(J)$. It follows that both $s_1, s_2$ are $2o$-ample ordered $2c$-asterisms, and that $(s_1, s_2)$ is a $2c$-gemini in $G$.

Let $Q = \{Q_1, \ldots, Q_{2c}\}$ be the $(2c)$-polypath in $G \setminus (L_{g_1} \cup L_{g_2})$ which along with $(s_1, s_2)$ satisfies (G3). For every $i \in \{1, 2\}$ and every $j \in [c]$, let $P^i_j$ be the shortest path in $G[V(s)]$ from $\pi(s_j - 1)$ to $\pi(s_j)$. So the interior of $P^i_j$ is contained in $L_s$, and since $s_i$ is a $2o$-ample, it follows that $P^i_j$ has length at least $2o + 2o$. Consequently, for every $j \in [c]$, $H_j = \pi(s_1(2j - 1) - P^1_j - s_1(2j) - Q_2j - \pi(s_2(2j) - P^2_j - s_2(2j - 1) - Q_2j - 1 - \pi(s_1(2j - 1)$ is a cycle in $G$ of length at least $4o + 4$. Moreover, for every $i \in \{1, 2\}$, since $s_i$ is a $2o$-ample $2c$-syzygy in $G$, by (SY), the paths $\{P^i_j : j \in [c]\}$ are pairwise disjoint and anticomplete in $G$. Hence, $H_1, \ldots, H_c$ are pairwise disjoint and anticomplete in $G$. But this violates the assumption that $G$ is $(c, o)$-perforated, and so completes the proof of Lemma 5.6. ■
We are now in a position to prove Theorem 5.1, which we restate:

**Theorem 5.1.** For all integers \( a, b, c, h, l, s, o, t \geq 1 \) and \( s \geq 0 \), there exist integers \( \Theta = \Theta(a, b, c, h, l, o, s, t) \geq 1 \) and \( \theta = \theta(a, b, c, h, l, o, s, t) \geq 1 \) with the following property. Let \( G \) be a \((c, o)\)-perforated graph and let \( \mathcal{I} \) be a collection of \( \Theta \) pairwise disentangled plain \((\leq b, \Theta)\)-bundles in \( G \). Then one of the following holds.

(a) \( G \) contains either \( K_4 \) or \( K_{1,1} \).

(b) There exists a plain \((s, l)\)-constellation in \( G \).

(c) There exists \( \mathcal{A} \subseteq \mathcal{I} \) with \( |\mathcal{A}| = a \) as well as \( \mathcal{H}_b \subseteq \mathcal{L}_b \) with \( |\mathcal{H}_b| = h \) for each \( b \in \mathcal{A} \), such that for all distinct \( b, b' \in \mathcal{A} \), \( S_b \cup V(\mathcal{H}_b) \) is anticomplete to \( S_{b'} \cup V(\mathcal{H}_{b'}) \) in \( G \).

**Proof.** Let \( \gamma = \gamma(c, l - 1, l, o, s) \geq 1 \) be as in Lemma 5.6 and let \( \phi = \phi(a, \max\{h, s(\gamma + 4l - 4)^l + 1\}) \geq 1 \) be given by Lemma 5.3. Let \( \beta(\gamma, \cdot, \cdot, \cdot, \cdot, \cdot, \cdot, \cdot) \) be as in Lemma 5.2, and define

\[
\Theta = \beta(b, \varphi, l, a, 1, s, t); \quad \theta = 2b(l - 1) + \varphi.
\]

We show that the above choices of \( \Theta \) and \( \theta \) satisfy Theorem 5.1. Suppose for a contradiction that none of the three outcomes of Theorem 5.1 holds.

By the choice of \( \Theta \) and \( \theta \), we can apply Lemma 5.2 to \( \mathcal{I} \). Note that Lemma 5.2(a) implies Theorem 5.1(a). Also, since all the bundles in \( \mathcal{I} \) are plain, it follows that Lemma 5.2(b) implies Theorem 5.1(b). Therefore, Lemma 5.2(c) holds. Specifically, we have:

(10) There exist \( \mathcal{A} \subseteq \mathcal{I} \) with \( |\mathcal{A}| = a \) as well as \( \mathcal{F}_b \subseteq \mathcal{L}_b \) with \( |\mathcal{F}_b| = \varphi \) for each \( b \in \mathcal{A} \), such that for all distinct \( b, b' \in \mathcal{A} \), \( S_b \) is anticomplete to \( S_{b'} \cup V(\mathcal{F}_{b'}) \) in \( G \).

Next, by the choice of \( \varphi \), we may apply Lemma 5.3 to \( \{\mathcal{F}_b : b \in \mathcal{A}\} \), and deduce that:

(11) For every \( b \in \mathcal{A} \), there exists a \( \max\{h, s(\gamma + 4l - 4)^l + 1\}\)-path in \( G \) such that for all distinct \( b, b' \in \mathcal{A} \), \( V(\mathcal{G}_b) \) is anticomplete to \( V(\mathcal{G}_{b'}) \) in \( G \), or for every \( L \in \mathcal{L}_b \) and every \( L' \in \mathcal{G}_{b'} \), there is an edge in \( G \) with an end in \( L \) and an end in \( L' \).

In particular, for every \( b \in \mathcal{A} \), one may pick \( \mathcal{H}_b \subseteq \mathcal{L}_b \) with \( |\mathcal{H}_b| = h \). Note that, for distinct \( b, b' \in \mathcal{A} \), if \( V(\mathcal{G}_b) \) is anticomplete to \( V(\mathcal{G}_{b'}) \) in \( G \), then by (10), \( S_b \cup V(\mathcal{H}_b) \) is anticomplete to \( S_{b'} \cup V(\mathcal{H}_{b'}) \). Consequently, from (11) and since Theorem 5.1(c) is assumed not to hold, it follows that:

(12) There are distinct \( b, b' \in \mathcal{A} \), such that for every \( L \in \mathcal{L}_b \) and every \( L' \in \mathcal{G}_{b'} \), there is an edge in \( G \) with an end in \( L \) and an end in \( L' \).

Henceforth, let \( b, b' \) be as in (12). Since \( |\mathcal{G}_b| = |\mathcal{G}_{b'}| \geq s(\gamma + 4l - 4)^l + 1 > \gamma + 4l - 4 \), we may choose \( \mathcal{G} \subseteq \mathcal{G}_b \) and \( \mathcal{G}' \subseteq \mathcal{G}_{b'} \) with \( |\mathcal{G}| = s(\gamma + 4l - 4)^l + 1 \) and \( |\mathcal{G}'| = \gamma + 4l - 4 \). It follows that both \( \mathcal{G} \) and \( \mathcal{G}' \) are plain paths in \( G \). For every path \( L \in \mathcal{G} \), let us say \( L \) is rigid if there exists a vertex \( x_L \in L \) as well as \( \mathcal{G}'_L \subseteq \mathcal{G}' \) with \( |\mathcal{G}'_L| = l \) such that \( x_L \) has a neighbor in every path in \( \mathcal{G}'_L \). Let \( \mathcal{R} \subseteq \mathcal{G} \) be the set of all rigid paths.

(13) We have \( |\mathcal{G} \setminus \mathcal{R}| \geq 2 \), that is, there are two distinct paths \( L_1, L_2 \in \mathcal{G} \) such that for each \( i \in \{1, 2\} \), every vertex in \( L_i \) has a neighbor in at most \( l - 1 \) paths in \( \mathcal{G}' \).

Suppose not. Then we have \( |\mathcal{R}| \geq s(\gamma + 4l - 4)^l \). For every \( L \in \mathcal{R} \), let \( x_L \in L \) and \( \mathcal{G}'_L \subseteq \mathcal{G}' \) with \( |\mathcal{G}'_L| = l \) be as in the definition of a rigid path. Since \( |\mathcal{G}'| = \gamma + 4l - 4 \), it follows that there exists \( \mathcal{S} \subseteq \mathcal{R} \subseteq \mathcal{G} \) with \( |\mathcal{S}| = s \) and \( \mathcal{L} \subseteq \mathcal{G}' \) with \( \mathcal{L} = l \) such that for every \( L \in \mathcal{S} \), we have \( \mathcal{G}'_L = \mathcal{L} \). Let \( \mathcal{S} = \{x_L : L \in \mathcal{S}\} \). Then every vertex in \( \mathcal{S} \) has a neighbor in every path in \( \mathcal{L} \). But now since both \( \mathcal{G} \) and \( \mathcal{G}' \) are plain, it follows that \( (\mathcal{S}, \mathcal{L}) \) is a plain \((s, l)\)-constellation in \( G \), and so Theorem 5.1(b) holds, a contradiction. This proves (13).

Let \( L_1, L_2 \in \mathcal{G} \) be as in (13). Let \( \mathcal{T} \) be the set of all paths \( L' \in \mathcal{G}' \) for which some vertex in \( \partial L_1 \cup \partial L_2 \) has a neighbor in \( L' \) in \( G \). Then by (13), we have \( |\mathcal{T}| \leq 4l - 4 \). Consequently, we
may choose $\gamma$ distinct paths $L_1', \ldots, L_s' \in G'$ such that for every $i \in \gamma$, $\partial L_1 \cup \partial L_2$ is anticomplete to $L_i$ in $G$. By (12), for every $i \in \gamma$, we may choose a shortest path $Q_i$ in $L_i'$ from a vertex $x_i^j \in L_i'$ with a neighbor in $L_1$ to a vertex $x_2^j \in L_2'$ with a neighbor in $L_2$. For $i \in \{1, 2\}$, let $S_i = \{x_i^j : j \in \gamma\}$. It follows that every vertex in $S_i$ has a neighbor in $L_i$ while $S_i$ is anticomplete to $\partial L_i$. Therefore, $g_i = (S_i, L_i)$ is an ordered $\gamma$-asterism in $G$ with $\tau_{g_i}(j) = x_i^j$ for every $j \in \gamma$. Also, by (13), $g_i$ is $(l - 1)$-meager.

Now, since both $G$ and $G'$ are plain, and by the choice of $Q_1, \ldots, Q_\gamma$, we conclude that $(g_1, g_2)$ is a pair of $(l - 1)$-meager ordered $\gamma$-asterisms in $G$ satisfying (G1) and (G2), and that $Q = \{Q_1, \ldots, Q_\gamma\}$ satisfies (G3). Hence, $(g_1, g_2)$ is a $\gamma$-gemini in $G$ where both $g_1$ and $g_2$ are $(l - 1)$-meager. But then Lemma 5.6 along with the choice of $\gamma$ implies that there exists a plain $(s, l)$-constellation in $G$, and so Theorem 5.1(b) holds, a contradiction. This completes the proof of Theorem 5.1. 

6. Transition graphs: a tale of an intuition coming true

In this section, we take a substantial step towards the proof of Theorem 3.2 by showing that:

**Theorem 6.1.** For all integers $c, o, t \geq 1$ and $s \geq 0$, there exist integers $\Sigma = \Sigma(c, o, s, t) \geq 0$ and $\Lambda = \Lambda(c, o, s, t) \geq 1$ with the following property. Let $G$ be a $(c, o)$-perforated graph. Assume that there exists a plain $(\Sigma, \Lambda)$-constellation in $G$. Then $G$ contains either $K_t$ or $K_{t,t}$, or there is a full $(s, o)$-occultation in $G$.

The proof of Theorem 6.1 is centered around a rather intuitive idea, the “matching/vertex-cover duality in transition graphs” described in Section 1.4. Our job here is to inject rigor and the main step will be taken in Lemma 6.3. But first we need to add another lemma to our arsenal, which will also be used in the next section.

**Lemma 6.2.** For all integers $l, m \geq 1$ and $s \geq 0$, there exists an integer $\psi = \psi(l, m, s) \geq 1$ with the following property. Let $G$ be a graph. Assume that there exists a $(\psi, l + m^2 - 1)$-constellation $c$ in $G$. Then for every integer $d \geq 1$, one of the following holds.

(a) $G$ contains a $(\leq d)$-subdivision of $K_m$ as a subgraph.

(b) There exists $S \subseteq S_i$ with $|S| = s$ and $L \subseteq S_i$ with $|L| = l$ such that for every $L \in L$, $(S, L)$ is a $d$-ample $s$-asterism in $G$.

**Proof.** Let $\psi = \psi(l, m, s) = \rho(\max\{m, s + 2l\}, 2, 2l^2 - 1)$; where $\rho(\cdot, \cdot, \cdot)$ is as in Theorem 2.1. For every $2$-subset $X$ of $S_i$, let $\Phi(X)$ be the set of all paths $L \in L_i$ for which there exists a path $R$ in $G$ of length at most $d + 1$ with $\partial R = X$ and $R^* \subseteq L$. It follows that the map $\Phi: (S_i^2) \rightarrow 2^{\Sigma}$ is well-defined. From the choice of $\psi$ and Theorem 2.1, we deduce that there exists $\mathbb{W} \subseteq L_i$ as well as $Z \subseteq S_i$ with $|Z| = \max\{m, s + 2l\}$, such that for every $2$-subset $X$ of $Z$, we have $\Phi(X) = \mathbb{W}$.

First, assume that $|\mathbb{W}| \geq m^2$. Let $M \subseteq Z$ with $|M| = m$. Then for every $2$-subset $X$ of $M$, one may choose a path $L_X \in \mathbb{W} = \Phi(X)$ such that the paths $\{L_X : X \in (M^2)\}$ are pairwise distinct, and hence disjoint. Also, from the definition of $\Phi$, it follows that for every $2$-subset $X$ of $M$, there exists a path $R_X$ in $G$ of length at most $d + 1$ with $\partial R_X = X$ and $R^*_X \subseteq L_X$. But then $G[\bigcup_{X \in (M^2)} R_X]$ contains a $(\leq d)$-subdivision of $K_m$ as a (spanning) subgraph, and so Lemma 6.2(a) holds, as desired.

Next, assume that $|\mathbb{W}| < m^2$. Then there exists $\mathbb{L} \subseteq L_i \setminus \mathbb{W}$ with $|\mathbb{L}| = l$. Pick a subset $S'$ of $Z$ with $|S'| = s + 2l$. For every $2$-subset $X$ of $S'$ and every path $L \in \mathbb{L}$, since we have $\Phi(X) = \mathbb{W}$, it follows from the definition of $\Phi$ that there is no path $R$ in $G$ of length at most $d + 1$ with $\partial L = X$ and $R^*_X \subseteq L$. In particular, since $d \geq 1$, it follows that every vertex in $V(\mathbb{L})$ has at most one neighbor in $S'$. Consequently, there exists $S \subseteq S'$ with $|S| = s$ which is anticomplete to $\partial \mathbb{L}$. Now for every $L \in \mathbb{L}$, every vertex in $S$ has a neighbor in $L$ while $S$ is anticomplete to
by Theorem 2.3 and the choice of \( \sigma \) of \( \psi \)), Lemma 6.3(a) does not hold, that is, \( \psi \neq \psi \). Now, define \( \tau \). Let \( G \) be a \( (c, o) \)-perforated graph and let \( \mathcal{L} \) be the unique \( (\sigma, \lambda) \)-constellation in \( G \). Then one of the following holds.

(a) \( G \) contains either \( K_t \) or \( K_t \).

(b) There exists an \( (o + 2) \)-ample, interrupted ordered \( s \)-asterism \( \sigma \) in \( G \) such that \( S_\sigma \subseteq S_\tau \), and for some \( L \in \mathcal{L} \), we have \( L \leq L \).

Proof. Let \( c, o, t \geq 1 \) be fixed. Let \( H \) be the unique 2-regular graph (up to isomorphism) with exactly \( c \) components, each on \( o + 2 \) vertices. Let \( m = m(H, o + 2, t) \) be as in Theorem 2.3 (note that here \( m \) only depends on \( c, o \) and \( t \)). Let \( \rho(\cdot, \cdot, \cdot) \) be as in Theorem 2.1 and let \( \beta(\cdot, \cdot, \cdot, \cdot, \cdot) \) be as in Lemma 5.2.

Consider the following recursive definition for \( \sigma \) and \( \lambda \). Let \( \sigma(c, o, 0, t) = 0 \) and \( \lambda(c, o, 0, t) = 1 \). For every \( s \geq 1 \), assuming \( \sigma' = \sigma(c, o, s - 1, t) \) and \( \lambda' = \lambda(c, o, s - 1, t) \) are defined, let

\[
\begin{align*}
\sigma_3 &= \sigma_3(c, o, s, t) = \beta(2, 2, \lambda', c, 1, \sigma', t); \\
\sigma_2 &= \sigma_2(c, o, s, t) = \rho(2\sigma_3, 2, 2^{2c} - 1); \\
\sigma_1 &= \sigma_1(c, o, s, t) = 2c + \sigma_2; \\
\lambda_2 &= \lambda_2(c, o, s, t) = 2^{2c+1}\sigma_3(2\lambda' - 1)\sigma_2^{2s}; \\
\lambda_1 &= \lambda_1(c, o, s, t) = 2^{2s}\lambda_2.
\end{align*}
\]

Now, define

\[
\begin{align*}
\sigma &= \sigma(c, o, s, t) = \psi(\lambda_1, m, \sigma_1); \\
\lambda &= \lambda(c, o, s, t) = \lambda_1 + m^2 - 1;
\end{align*}
\]

where \( \psi = \psi(\cdot, \cdot, \cdot) \) is as in Lemma 6.2. We will prove, by induction on \( s \), that the above values of \( \sigma \) and \( \lambda \) satisfy Lemma 6.3. If \( s = 0 \), then Lemma 6.3(b) is immediately seen to hold. Assume that \( s \geq 1 \).

Let \( G \) be a \( (c, o) \)-perforated graph and let \( \mathcal{L} \) be the unique \( (\sigma, \lambda) \)-constellation in \( G \). Suppose that Lemma 6.3(a) does not hold, that is, \( G \) contains neither \( K_t \) nor \( K_{t,t} \). Since \( G \) is \( (c, o) \)-perforated, it follows that \( G \) contains no induced subgraph isomorphic to a subdivision of \( H \). Therefore, by Theorem 2.3 and the choice of \( m \), it follows that \( G \) contains no subgraph isomorphic to a

Figure 7. The transition graph \( T_a \) of the 4-asterism \( a \) in Figure 4 with the \( a \)-routes \( x_1-u_7-u_6-u_5-x_2, x_1-u_7-u_8-u_9-u_{10}-x_3, x_2-u_{12}-u_{11}-u_{10}-x_3, \) \( x_2-u_{13}-u_{14}-u_{15}-u_{16}-x_4 \) and \( x_3-u_{18}-u_{17}-u_{16}-x_4 \) corresponding to the edges of \( T_a \). Note that the unique \( a \)-route \( x_1-u_7-\cdots-u_{16}-x_4 \) from \( x_1 \) to \( x_4 \) contains neighbors of both \( x_2 \) and \( x_3 \).
implies that there exists \( \sigma \in L \) such that for every \( L \in L \), \( f_L = (S, L) \) is an \((o + 2)\)-ample \( \sigma \)-asterism in \( G \). In particular, \( f = (S, L_1) \) is a plain \((\sigma_1, \lambda_1)\)-constellation in \( G \).

Since \( |L_1| = \lambda_1 = 2\sigma_3^2 \lambda_2 \), it follows that:

(14) There exists \( L_2 \subseteq L \) with \( |L_2| = \lambda_2 \) as well as \( E_2 \subseteq \binom{|S|}{2} \), such that for every \( L \in L_2 \), we have \( E(T_{f_L}) = E_2 \).

Henceforth, let \( L_2 \) and \( E_2 \) be as in (14). Let \( T \) be the graph with \( V(T) = S \) and \( E(T) = E_2 \). Then (14) implies that \( T_{f_L} = T \) for every \( L \in L_2 \). We deduce:

(15) \( T \) does not have a matching of cardinality \( c \).

Suppose for a contradiction that there exists a matching \( \{x_1x'_1, \ldots, x cx'_c\} \subseteq E(T) \) of cardinality \( c \) in \( T \). Since \( |L_2| = \lambda_2 \geq 2 \), we may choose two distinct paths \( L_1, L_2 \in L_2 \). Then we have \( \{x_1x'_1, \ldots, x cx'_c\} \subseteq E(T_{f_{L_1}}) = E(T_{f_{L_2}}) \). Also, since \( f_{L_1} \) and \( f_{L_2} \) are both \((o + 2)\)-ample, \( f \) is plain, and from the definition of the transition graph, it follows that for every \( i \in \{1, 2\} \) and \( j \in [c] \), there exists an \( f_{L_i} \)-route \( R_{i,j} \) of length at least \( o + 4 \) from \( x_j \) to \( x'_j \), such that for all distinct \( j, j' \in [c] \), \( R_{1,j} \cup R_{2,j} \) and \( R_{1,j'} \cup R_{2,j'} \) are disjoint and anticomplete cycles in \( G \), each of length at least \( 2o + 8 \). In other words, \( \{R_{1,j} \cup R_{2,j} : j \in [c]\} \) is a collection of \( c \) pairwise disjoint and anticomplete cycles in \( G \), each of length at least \( 2o + 8 \). But this violates the assumption that \( G \) is \((c, o)\)-perforated, and so proves (15).

By (15), there exists a vertex cover \( X \subseteq S = V(T) \) for \( T \) with \( |X| < 2c \). Consequently, \( S \setminus X = V(T) \setminus X \) is a stable set in \( T \). Moreover, we have:

(16) Let \( L \in L_2 \). Then for every \( f_{L} \)-route \( R \), there exists a vertex \( x \in X \) which has a neighbor in \( R^* \).

Suppose not. Then we may pick \( L \in L_2 \) and a minimal \( f_{L} \)-route \( R \) such that \( X \) is anticomplete to \( R^* \). Let \( z, z' \in S \) be the ends of \( R \); so \( z, z' \in S \setminus X = V(T) \setminus X \). Since \( f_{L} \) is \((o + 2)\)-ample and from the minimality of \( R \), it follows that \( S \setminus \{X \cup \{z, z'\}\} \) is anticomplete to \( R^* \). We conclude that \( S \setminus \{z, z'\} = V(T_{f_L}) \setminus \{z, z'\} \) is anticomplete to \( R^* \). But then from the definition of the transition graph, it follows that \( z, z' \in E(T_{f_L}) = E(T) \), a contradiction with the fact that \( V(T) \setminus X \) is a stable set in \( T \). This proves (16).

In view of (16), for every \( L \in L_2 \) and all distinct \( z, z' \in S \setminus X \), we may choose a minimal non-empty subset \( \Phi_{L} (\{z, z'\}) \) of \( X \) such that for every \( f_{L} \)-route \( R \) from \( z \) to \( z' \), there exists a vertex \( x \in \Phi_{L} (\{z, z'\}) \) which has a neighbor in \( R^* \). It follows that, for every \( L \in L_2 \), the map \( \Phi_{L} : \binom{S \setminus X}{2} \rightarrow 2^X \setminus \{\emptyset \} \) is well-defined. Since \( |S \setminus X| = \sigma_1 - 2c = \sigma_2 = \rho(2\sigma_3, 2, 2^{2c} - 1) \), applying Theorem 2.1 yields the following:

(17) For every \( L \in L_2 \), there exists \( Y_L \subseteq X \) and \( Z_L \subseteq S \setminus X \) such that:

• we have \( Y_L \neq \emptyset \) and \( |Z_L| = 2\sigma_3 \); and

• for all distinct \( z, z' \in Z_L \), we have \( \Phi_{L} (\{z, z'\}) = Y_L \).

Combining (17) with the fact that \( |L_2| = \lambda_2 = 2^{2c + 1} \sigma_3 (2\lambda - 1) \sigma_2^{2\tau_3} \), it follows from a pigeonhole argument that for several choices of \( L \in L_2 \) for which the sets \( Y_L \) associated with them are all the same, and so are the sets \( Z_L \). More precisely, we deduce:
(18) There exist $L_3 \subseteq L_2$, $Y \subseteq X$ and $Z \subseteq S \setminus X$, such that:

- we have $|L_3| = \sigma_3(4\lambda - 2)$, $Y \neq \emptyset$ and $|Z| = 2\sigma_3$; and
- for every $L \in L_3$ and all distinct $z, z' \in Z$, we have $\Phi_L(\{z, z'\}) = Y$.

By the first bullet of (18), we may fix a partition $\{L_3^i : i \in [\sigma_3]\}$ of $L_3$ into $(4\lambda - 2)$-subsets, a vertex $y \in Y$, and a partition $\{\{z_i, z'_i\} : i \in [\sigma_3]\}$ of $Z$ into $2$-subsets. By the second bullet of (18), for every $L \in L_3$ and every $i \in [\sigma_3]$, we have $y \in Y = \Phi_L(\{z_i, z'_i\})$. This, together with the minimality of $\Phi_L(\{z_i, z'_i\})$, implies that for every $L \in L_3$ and $i \in [\sigma_3]$, there exists an $I_L$-route $Q_{i,L}$ from $z_i$ to $z'_i$ such that, writing $R_{i,L} = Q_{i,L}^{-1}$, we have that $y$ is the only vertex in $Y$ with a neighbor in $R_{i,L}$.

Now, for every $i \in [\sigma_3]$, let $b_i$ be the $(2, 4\lambda - 2)$-bundle in $G$ with $S_{b_i} = \{z_i, z'_i\}$ and $L_{b_i} = \{R_{i,L} : L \in L_3^i\}$. We claim that:

(19) There exists $i \in [\sigma_3]$, $S' \subseteq Z \setminus \{z_i, z'_i\}$ with $|S'| = \sigma'$ and $G \subseteq L_{b_i}$ with $|G| = \lambda'$ such that $(S', G)$ is a plain $(\sigma', \lambda')$-constellation in $G$.

Recall that $\sigma_3 = \beta(2, 2, \lambda', c, 1, \sigma', t)$. Thus, we may apply Lemma 5.2 to $\mathbf{b} = \{b_i : i \in [\sigma_3]\}$. Since $G$ is assumed not to contain $K_t$ or $K_{t,t}$, it follows that Lemma 5.2(a) does not hold. Assume that Lemma 5.2(c) holds. Then exists $I \subseteq [\sigma_3]$ with $|I| = c$ as well as $L_1^i, L_2^i \in L_3$ for each $i \in I$, such that for all distinct $i, j \in I$, $\{z_i, z'_i\}$ is antimcomplete to $\{z_j, z'_j\}$ and $R_{i,L_1^i} \cup R_{j,L_2^j}$. Since $L_3$ is a plain polypath and $I_L$ is $(o + 2)$-ample for every $L \in L_3$, it follows that for all distinct $i, j \in I$, $Q_{i,L_1^i} \cup Q_{j,L_2^j}$ and $Q_{i,L_1^i} \cup Q_{j,L_2^j}$ are two disjoint and antimcomplete cycles in $G$, each of length at least $2o + 8$. In other words, $\{Q_{i,L_1^i} \cup Q_{j,L_2^j} : i \in I\}$ is a collection of $c$ pairwise disjoint and antimcomplete cycles in $G$, each of length at least $2o + 8$, a contradiction with $G$ being $(c, o)$-perforated. It follows that Lemma 5.2(b) holds, that is, there exists $i \in [\sigma_3]$, $S' \subseteq Z \setminus S_{b_i} = Z \setminus \{z_i, z'_i\}$ with $|S'| = \sigma'$ and $G \subseteq L_{b_i}$ with $|G| = \lambda'$ such that $(S', G)$ is a $(\sigma', \lambda')$-constellation in $G$. In addition, $(S', G)$ is plain, because $f$ is. This proves (19).

Henceforth, let us fix $i \in [\sigma_3]$, $S' \subseteq Z \setminus \{z_i, z'_i\}$ and $G \subseteq L_{b_i}$ as given by (19). Now we apply the induction hypothesis to show that:

(20) For some $L \in L_3^i$, there exists an $(o + 2)$-ample, interrupted ordered $(s - 1)$-asterism $a'$ in $G$ such that $S_{a'} \subseteq S'$ and $L_{a'} \subseteq R_{i,L}$.

By (19), $c' = (S', G)$ is a plain $(\sigma', \lambda')$-constellation in $G$. Since $G$ is assumed not to contain $K_t$ or $K_{t,t}$, by the induction hypothesis applied to $c'$, there exist an $(o + 2)$-ample, interrupted ordered $(s - 1)$-asterism $a'$ in $G$ such that $S_{a'} \subseteq S_{c'} = S'$, and for some $L' \in L_{c'} = G \subseteq L_{b_i}$, we have $L_{a'} \subseteq L'$. From the definition of $b_i$, it follows that for some $L \in L_3^i$, we have $L_{a'} \subseteq R_{i,L}$. This proves (20).

Let $L \in L_3^i$ be as in (20). Then we may choose an $(o + 2)$-ample, interrupted ordered $(s - 1)$-asterism $a'$ in $G$ such that $S_{a'} \subseteq S'$, $L_{a'} \subseteq R_{i,L}$, and $L_{a'}$ is maximal with respect to inclusion. By (19), every vertex in $S'$ has a neighbor in $R_{i,L}$ in $G$. Also, recall that the vertex $y \in X \subseteq S' \setminus Z \subseteq S' \setminus S'$ has a neighbor in $R_{i,L} = Q_{i,L}^{-1}$. In fact, since $I_L$ is $(o + 2)$-ample, it follows that every vertex in $S' \setminus \{y\}$ has a neighbor in $R_{i,L}$ and $S' \setminus \{y\}$ is antimcomplete to the ends of $\partial R_{i,L}$. As a result, $a^+ = (S' \setminus \{y\}, R_{i,L})$ is a $(\sigma' + 1)$-asterism in $G$ such that $S_{a^+} \subseteq S' = S_{a'} \setminus \{y\}$ and $L_{a^+} \subseteq R_{i,L} = L_{a'}$. We further deduce that:

(21) $a'$ is a $(a^+ + y, s - 1)$-candidate in $G$ and $y$ is a cherry on top of $a^+|S_{a'}$ in $G$.

From the maximality of $L_{a'} \subseteq R_{i,L}$, it follows immediately that $a^+$, $a'$ and $y$ satisfy (CA), and so $a'$ is a $(a^+, y, s - 1)$-candidate in $G$. Let us now prove that $y$ is a cherry on top of $a^+|S_{a'}$ in $G$. We need to show that $a^+|S_{a'}$ and $y$ satisfy (CH1) and (CH2). Observe that (CH1) follows from the fact that $L_{a^+}|S_{a'} = L_{a^+}$. To see (CH2), let $P$ be an open $a^+|S_{a'}$-piece. It follows that
\begin{proof}

The proof of Theorem 6.1.

\[
\begin{aligned}
P \text{ is the interior an } f_L \text{-route between two vertices in } S' \cup \{z_i, z'_i\}. \quad \text{On the other hand, since}
\end{aligned}
\]

\[
\begin{aligned}
S' \cup \{z_i, z'_i\} \subseteq Z \text{ and } \mathcal{L}_2 \subseteq \mathcal{L}_3, \quad \text{it follows from the second bullet of (18) that some vertex in}
\end{aligned}
\]

\[
\begin{aligned}
Y \text{ has a neighbor in } P. \quad \text{But then from } P \subseteq R_{i,L} \subseteq Q_{i,L} \text{ and the choice of } Q_{i,L}, \text{ we conclude that}
\end{aligned}
\]

\[
\begin{aligned}
y \text{ has a neighbor in } P. \quad \text{This proves (21).}
\end{aligned}
\]

We can now finish the proof. Note that \( a^+ \) is \((o + 2)\)-ample, because \( f_L \) is. Therefore, since \( o + 2 \geq 3 \), in view of (21), we can apply Lemma 4.2 to \( a^+, a' \) and \( y \), and deduce that \( a = \text{Cher}(a', y) \) is an \((o + 2)\)-ample, interrupted ordered \( s^\circ \)-asterism in \( G \) with \( S_0 \subseteq S_a^+ = S' \cup \{y\} \subseteq S \subseteq S' \), and \( L_0 = L_a^+ = R_{i,L} \subseteq L \) where \( L \in \mathcal{L}_2 \subseteq \mathcal{L}_3 \subseteq \mathcal{L}_2 \subseteq \mathcal{L}_1 \subseteq \mathcal{L}_\epsilon \). Hence, Lemma 6.3(b) holds. This completes the proof of Lemma 6.3.
\end{proof}

Now Theorem 6.1 becomes almost immediate:

\begin{proof}[Proof of Theorem 6.1]

Let \( \Sigma = \Sigma(c, o, s, t) = \sigma(c, o, s^\circ, t) \) and \( \Lambda = \Lambda(c, o, s, t) = \lambda(c, o, s^\circ, t) \), where \( \sigma(\cdot, \cdot, \cdot, \cdot) \) and \( \lambda(\cdot, \cdot, \cdot, \cdot) \) are as in Lemma 6.3. Let \( G \) be a \((c, o)\)-perforated graph and let \( \xi \) be a \((\Sigma, \Lambda)\)-constellation in \( G \). Assume that \( G \) does not contain \( K_l \) or \( K_{l,l} \). By Lemma 6.3(b), there exists an \((o + 2)\)-ample, interrupted ordered \( s^\circ \)-asterism in \( G \). Since \( o + 2 \geq 3 \), by Theorem 4.1, there is a full \((s, o)\)-occultation in \( G \). This completes the proof of Theorem 6.1.
\end{proof}

7. Patch \& Match

Here we obtain the last main ingredient in the proof of Theorem 3.2:

\begin{theorem}

For all integers \( c, l, o, s, t \geq 1 \), there exist an integer \( \Omega = \Omega(c, l, o, s, t) \geq 1 \) with the following property. Let \( G \) be a \((c, o)\)-perforated graph. Assume that there exists a strong \( \Omega \)-block in \( G \). Then one of the following holds.

(a) \( G \) contains either \( K_l \) or \( K_{l,l} \).

(b) There exists a plain \((s, l)\)-constellation in \( G \).

We need a couple of definitions and a lemma. Let \( G \) be a graph and let \( d \geq 0 \) and \( r \geq 1 \) be integers. For \( X \subseteq V(G) \), by a \((d, r)\)-patch for \( X \) in \( G \) we mean a \((1, r)\)-bundle \( p \) in \( G \) where:

(P1) we have \( S_p \subseteq V(G) \setminus V(L_p) \);

(P2) every path \( L \in L_p \) has length at least \( d \); and

(P3) for every \( L \in L_p \), one may write \( \partial L = \{x_L, y_L\} \) such that \( L \cap X = \{x_L\} \) and \( N_L(S_p) = \{y_L\} \).

Also, by a \((d, r)\)-match for \( X \) in \( G \) we mean an \( r \)-polypath \( M \) in \( G \) such that:

(M1) every path \( L \in M \) has length at least \( d \); and

(M2) \( V(M) \cap X = \partial M \).

\begin{lemma}

For all integers \( d, s \geq 0 \) and \( l, m, r, r' \geq 1 \), there exists an integer \( \eta = \eta(d, l, m, r, r', s) \geq 1 \) with the following property. Let \( G \) be a graph, let \( X \subseteq V(G) \) and let \( \mathcal{P} \) be a \((d, \eta)\)-patch for \( X \) in \( G \). Then one of the following holds.

(a) \( G \) contains a \((d + 1)\)-subdivision of \( K_m \) as a subgraph.

(b) There exists a plain \((s, l)\)-constellation in \( G \).

(c) There exists a plain \((2(d + 1), r)\)-match \( M \) for \( X \) in \( G \) such that \( V(M) \subseteq V(p) \).

(d) There exists a plain \((d, r')\)-patch \( q \) for \( X \) in \( G \) such that \( V(q) \subseteq V(p) \).

\end{lemma}

\begin{proof}

Let \( l, m, r, r' \geq 1 \) and \( s \geq 0 \) be fixed. In order to define \( \eta \), first we recursively define a sequence \( \{\zeta_d \colon d \geq 0\} \), as follows. Let

\[
\zeta_0 = \mu(\max\{m, 4r, r' + 1\});
\]

where \( \mu(\cdot) \) is as in Theorem 2.7. Let \( \psi = \psi(1, m, (4r)^{l-1}(s+l-1)) \) be as in Lemma 6.2. For every \( d \geq 1 \), let

\[
\zeta_d = \beta(1, 1, 1, \zeta_{d-1}, m^2, \psi, m^2);
\]

where \( \beta(\cdot, \cdot, \cdot, \cdot, \cdot, \cdot) \) is as in Lemma 5.2. This concludes the definition of \( \zeta_d \) for all \( d \geq 0 \).
\end{proof}
Now, we claim that for every \( d \geq 0 \),
\[
\eta(d, l, m, r, r', s) = \zeta_{d+1}
\]
satisfies Lemma 7.2. Suppose not. Choose \( d \geq 0 \) minimum such that the above value of \( \eta(d, l, m, r, r', s) \) fails to satisfy Lemma 7.2.

Let \( G \) be a graph, let \( X \subseteq V(G) \) and let \( p \) be a \((d, \eta(d, l, m, r, r', s))\)-patch for \( X \) in \( G \). For every \( L \in \mathcal{L}_p \), let \( \partial L = \{x_L, y_L\} \) be as in (P3). We claim that:

\[ \tag{22} \text{There exist } \mathcal{P} \subseteq \mathcal{L}_p \text{ with } |\mathcal{P}| = \zeta_d \text{ such that for all distinct } L, L' \in \mathcal{P}, x_L \text{ is anticomplete to } L' \text{ in } G. \]

For each \( L \in \mathcal{L}_p \), let \( b_L \) be the \((1,1)\)-bundle in \( G \) with \( S_{b_L} = \{x_L\} \) and \( L_{b_L} = \{L\} \). Then \( \mathfrak{B} = \{b_L : L \in \mathcal{L}_p\} \) is a collection of \( \eta(d, l, m, r, r', s) = \zeta_{d+1} \) pairwise disentangled \((1,1)\)-bundles in \( G \). Now, the definition of \( \zeta_d \) for \( d \geq 1 \) allows for an application of Lemma 5.2 to \( \mathfrak{B} \), which implies that one of the following holds.

- \( G \) contains either \( K_{m^2} \) or \( K_{m^2,m^2} \).
- There exist \( \mathfrak{M} \subseteq \mathfrak{B} \) with \( |\mathfrak{M}| = m^2 \) as well as \( S \subseteq \bigcup_{b \in \mathfrak{M}} S_b \) with \( |S| = \psi \), such that for every \( b \in \mathfrak{M} \), there exists \( G_b \subseteq L_b \) with \( |G_b| = 1 \) for which \( (S, G_b) \) is a \((\psi,1)\)-constellation in \( G \). As a result, \( (S, \bigcup_{b \in \mathfrak{M}} G_b) \) is a \((\psi,m^2)\)-constellation in \( G \).
- There exist \( \mathfrak{M} \subseteq \mathfrak{B} \) with \( |\mathfrak{M}| = \zeta_d \) as well as \( \mathcal{F}_b \subseteq L_b \) with \( |\mathcal{F}_b| = 1 \) for each \( b \in \mathfrak{M} \), such that for all distinct \( b, b' \in \mathfrak{M} \), \( S_b \) is anticomplete to \( S_{b'} \cup V(\mathcal{F}_{b'}) \) in \( G \).

If the first bullet above holds, then \( G \) contains a \((\leq 1)\)-subdivision of \( K_m \) as a subgraph, and so Lemma 7.2(a) holds, a contradiction. Assume that the second bullet above holds. Then there exists \( L \subseteq \mathcal{L}_p \) with \( |L| = m^2 \) as well as \( S \subseteq \{x_L : L \in \mathcal{L}_p \setminus L\} \) with \( |S| = \psi \) such that \( c = (S, L) \) is an \((\psi,m^2)\)-constellation in \( G \). Now we can apply Lemma 6.2 to \( c \). Since Lemma 7.2(a) is assumed not to hold, it follows that Lemma 6.2(b) holds, that is, there exists \( S' \subseteq S \) with \( |S'| = (4r)^{l-1}(s + l - 1) \) and \( L \subseteq L' \subseteq V(G) \setminus X \) such that \( g = (S', L) \) is a \((d+1)\)-ample ((4r)\(^{l-1}(s + l - 1)\))-asterism in \( G \). In particular, \( g \) is 1-meager. So one may apply Lemma 5.5 to \( g \). This time, since Lemma 7.2(b) is assumed not to hold, it follows that Lemma 5.5(a) holds, and so there exists a \( 4r \)-syzygy \( s \) in \( G \) with \( S_s \subseteq S' \) and \( L_s \subseteq L \). Also, \( s \) is \((d+1)\)-ample, because \( g \) is. Let \( a \) be the end of \( L_a \subseteq L \) for which \( s \) satisfies (SY). For every \( i \in [r] \), let \( M_i \) be the shortest path in \( G[V(s_i)] \) from \( \pi_a(4i - 3) \) to \( \pi_a(4i - 1) \) with \( M_i \subseteq S_s \); in fact, we have \( M_0 \subseteq L_0 \subseteq L'' \subseteq V(G) \setminus X \). Since \( s \) is \((d+1)\)-ample and from (SY), it follows that \( M_1, \ldots, M_r \) are pairwise disjoint and anticomplete, each of length at least \( 2(d + 1) > 2d + 1 \). Thus, \( M \) is a plain \( r \)-polypath in \( G \) such that every path in \( M \) has length at least \( 2(d + 1) \). Also, we have \( V(M) \cap X = \{\pi_a(4i - 3), \pi_a(4i - 1) : i \in [r]\} = \partial M \). From this, \((M1)\) and \((M2)\), we conclude that \( M \) is a plain \((2(d + 1), r)\)-match for \( X \) with \( V(M) \subseteq \partial \mathcal{L}_p \cup L'' \subseteq V(p) \). But now Lemma 7.2(c) holds, a contradiction. It follows that the third bullet above holds. Let \( \mathcal{P} = \{L \in \mathcal{L}_p : b_L \in \mathfrak{M}\} \). Then we have \( \mathcal{P} \subseteq \mathcal{L}_p \) with \( |\mathcal{P}| = \zeta_d \), and for all distinct \( L, L' \in \mathcal{P}, x_L \text{ is anticomplete to } L' \text{ in } G \). This proves \((22)\).

Henceforth, let \( \mathcal{P} \subseteq \mathcal{L}_p \) be as in \((22)\). Let \( S = \{x_L : L \in \mathcal{P}\} \). Then \( S \) is a stable set in \( G \) of cardinality \( \zeta_d \).

\[ \tag{23} \text{We have } d \geq 1. \]

Suppose for a contradiction that \( d = 0 \). Then \( |S| = \zeta_0 = \mu(\max\{4r, r', m\}) \). Also, by (P3), \( G' = G[S \cup V(\mathcal{P}) \cup S_p] \) is connected. So we can apply Theorem 2.7 to \( G' \) and \( S \subseteq V(G') \). Since Lemma 7.2(a) does not hold, \( G \) does not contain \( K_m \). It follows that there exists an induced subgraph \( H \) of \( G' \) for which one of the following holds.

- \( H \) is a path in \( G \) with \( |H \cap S| = 4r \).
- \( H \) is either a caterpillar or the line graph of a caterpillar in \( G \) with \( |H \cap S| = 4r \) and \( H \cap S = \mathcal{Z}(H) \).
\begin{itemize}
\item H is a subdivided star with root z such that \(|H \cap S| = r' + 1| \) and \(Z(H) \subseteq H \cap S \subseteq Z(H) \cup \{z\} \).
\end{itemize}

Assume that one of the first two bullets above holds. Then since \(S\) is a stable set in \(G\), one may readily observe that there exists a plain \((2, r)\)-match \(M\) for \(S \subseteq X\) in \(G\) with \(V(M) \subseteq V(H) \subseteq V(G') = S \cup V(P) \cup S_p\). But then \(M\) is a plain \((2, r)\)-match for \(X\) in \(G\) with \(V(M) \subseteq V(p)\), and so Lemma 7.2(c) holds, a contradiction. Now assume that the third bullet above holds. Then one may pick a set \(Q\) of \(r'\) pairwise distinct components of \(H \setminus \{z\}\). It follows that \(Q\) is a plain \(r'\)-polypath in \(G\). Consequently, \(q = \{\{z\}, Q\}\) is a plain \((0, r')\)-patch for \(S \subseteq X\) in \(G\) with \(V(q) \subseteq V(H) \subseteq V(G') = S \cup V(P) \cup S_p \subseteq V(p)\), and so Lemma 7.2(d) holds, again a contradiction. This proves (23).

In view of (23), for every \(L \in \mathcal{P} \subseteq \mathcal{L}_p\), \(L\) has non-zero length, and so \(x_L\) has a unique neighbor \(x'_L\) in \(L \setminus \{x_L\}\). Let \(X' = \{x'_L : L \in \mathcal{P}\}\), and let \(p' = (X', \{L \setminus \{x_L\} : L \in \mathcal{P}\})\). Then it is straightforward to check that \(p'\) is a \((d - 1, \zeta_d)\)-patch for \(X'\) in \(G\). This, along with (23) and the definition of \(\eta\), implies that \(p'\) is a \((d - 1, \eta(d - 1, l, m, r, r', s))\)-patch for \(X'\) in \(G\). Also, we have \(V(p') \subseteq V(p)\). Now, from the minimality of \(d\), it follows that

- either there is a plain \((2d, r)\)-match \(M'\) for \(X'\) in \(G\) with \(V(M') \subseteq V(p') \subseteq V(p)\); or
- there is a plain \((d - 1, r')\)-patch \(q'\) for \(X'\) in \(G\) with \(V(q') \subseteq V(p') \subseteq V(p)\).

In the former case, by (23), each path in \(M'\) has non-zero length, and so for every \(M \in \mathcal{M}'\), there are two distinct paths \(K_M, L_M \in \mathcal{P}\) such that \(\partial M = \{x'_K, x'_L\}\); let \(M^+ = x_{K_M}x'_Kx_{L_M}x'_Lx_{L_M}\). But then by (22), \(M = \{M^+ : M \in \mathcal{M}'\}\) is a plain \((2d + 1)\)-match for \(X\) in \(G\) such that \(V(M) \subseteq V(M') \cup \partial \mathcal{L}_p \subseteq V(p)\), and Lemma 7.2(c) holds, a contradiction. Moreover, in the latter case, by (P3), for each \(Q \in \mathcal{Q}'\), there exists exactly one path \(R_Q \in \mathcal{P}\) such that \(Q \cap X' = \partial Q \cap X' = \{x'_R\}\), and assuming \(y_Q\) to be the other end of \(Q\) (possibly \(x'_R = y_Q\)), we have \(N_Q(S_q) = \{y_Q\}\). Let \(Q^+ = x_{R_Q}x'_Ry_Q\). Then by (22), \(q = (S_q, \{Q^+ : Q \in \mathcal{Q}'\})\) is a plain \((d, r')\)-patch for \(X\) in \(G\) with \(S_q \cup V(\mathcal{L}_q) \subseteq V(q') \cup \partial \mathcal{L}_p \subseteq V(p)\). But now Lemma 7.2(d) holds, again a contradiction. This completes the proof of Lemma 7.2.

We can now prove the main result of this section:

**Proof of Theorem 7.1.** Let \(H\) be the unique 2-regular graph (up to isomorphism) with exactly \(c\) components, each on \(o + 2\) vertices. Let \(m = m(H, o + 2, t)\) be as in Theorem 2.3 (note that here \(m\) only depends on \(c\), \(o\) and \(t\)). Let

\[
\Theta = \Theta(c, 2, c, 2, l, o, s, t);
\]

\[
\theta = \theta(c, 2, c, 2, l, o, s, t);
\]

be as in Theorem 5.1, and let

\[
\eta = \eta(o - 1, l, m, \theta, \theta, s)
\]

be as in Lemma 7.2. Define

\[
\Omega = \Omega(c, l, o, s, t) = \kappa(o, \max\{2\Omega, \eta\}, m)
\]

where \(\kappa = \kappa(\ldots, \cdot, \cdot)\) is as in Theorem 2.5. We prove that the above value of \(\Omega\) satisfies Theorem 7.1.

Let \(G\) be a \((c, o)\)-perforated graph and let \(B\) be a strong \(\Omega\)-block in \(G\). Suppose for a contradiction that \(G\) contains neither \(K_t\) nor \(K_{t+t}\), and there is no plain \((s, l)\)-constellation in \(G\). Since \(G\) is \((c, o)\)-perforated, it follows that \(G\) contains no induced subgraph isomorphic to a subdivision of \(H\). Therefore, by Theorem 2.3 and the choice of \(m\), \(G\) contains no subgraph isomorphic to a \((\leq o)\)-subdivision of \(K_m\). It is convenient to sum up all this in one statement:
Therefore, by (P1), (P2) and (P3), for every third bullet of (24), respectively, we deduce that for every $x \in L_S$ above, let $b_i = x$ but they are distinct from $o \in G$. Let $L_i = \{x_L : i \in [\Theta]\}$. It follows that $L_i$ is an $\eta$-polypath in $G$ such that
- for every $i \in [\Theta]$, every path $p \in P_i$ has length at least $o + 1 \geq 2$; and
- $V(P_1), \ldots, V(P_\Theta)$ are pairwise disjoint in $G$.

For each $i \in [\Theta]$, let $L_i = \{x_L : i \in [\Theta]\}$. Also, for every $L \in L_i$, let $x_L$ and $y_L$ be the (unique) neighbors of $x_i$ and $y_i$ in $P$, respectively; so we have $\partial L = \{x_L, y_L\}$ (note that $x_L, y_L$ might be the same, but they are distinct from $x_i$ and $y_i$). Let $X_i = \{x_L : L \in L_i\}$. It follows that $L_i$ is an $\eta$-polypath in $G$ such that
- $y_i \in V(G) \setminus V(L_i)$;
- every path $L \in L_i$ has length at least $o - 1$; and
- $L \cap X_i = \{x_L\}$ and $N_L(y_i) = \{y_L\}$.

Therefore, by (P1), (P2) and (P3), for every $i \in [\Theta]$, the $(1, \eta)$-bundle $p_i = \{y_i, L_i\}$ is an $(o - 1, \eta)$-patch for $X_i$ in $G$. This, along with the choice of $\eta$, allows for an application of Lemma 7.2 to $X_i$ and $p_i$. Since Lemma 7.2(a) and Lemma 7.2(b) violate the second and the third bullet of (24), respectively, we deduce that for every $i \in [\Theta]$, one of the following holds.
- There is a plain $(2o, \theta)$-match $M_i$ for $X_i$ in $G$ with $V(M_i) \subseteq V(p_i) \subseteq V(G) \setminus \{x_i\}$. See Figure 8, Left.
- There is a plain $(o - 1, \theta)$-match $q_i$ for $X_i$ in $G$ with $V(q_i) \subseteq V(p_i) \subseteq V(G) \setminus \{x_i\}$ (note that $S_q \subseteq X_i$ is also possible). See Figure 8, Middle and Right.

Now, for each $i \in [\Theta]$, we define the plain $(\leq 2, \theta)$-bundle $b_i$ as follows. In the former case above, let $S_{b_i} = \{x_i\}$ and let $\mathcal{L}_{b_i} = M_i$, and in the latter case, let $S_{b_i} = S_q \cup \{x_i\}$ and let $\mathcal{L}_{b_i} = L_i$. It follows that $\Sigma = \{b_1, \ldots, b_\Theta\}$ is a collection of $\Theta$ pairwise disentangled plain $(\leq 2, \theta)$-bundles in $G$. Given the choices of $\Theta$ and $\theta$, we can apply Theorem 5.1 to $\Sigma$, which combined with the first and third bullet of (24) implies that there exists $I \subseteq [\Theta]$ with $|I| = c$ as well as $H_i \subseteq L_i$, with $|H_i| = 2$ for each $i \in I$, such that for all distinct $i, i' \in I$, $S_{b_i} \cup V(H_i)$ is anticomplete to $S_{b_{i'}} \cup V(H_{i'})$ in $G$. In particular, for every $i \in I$, there is a cycle $H_i$ in $G[S_{b_i} \cup V(H_{i'})]$ of length at least $2o + 2$. But now $H_1, \ldots, H_c$ comprise $c$ pairwise disjoint and
anticomplete cycles in $G$, each of length at least $o + 2$, which violates the assumption that $G$ is $(c, o)$-perforated. This completes the proof of Theorem 7.1.

8. THE LONG-AWAITED CONCLUSION

Eventually, we can bring everything together and give a proof of Theorem 3.2:

**Theorem 3.2.** For all integers $c, o, t \geq 1$ and $s \geq 0$, there exists an integer $\tau = \tau(c, o, s, t) \geq 1$ such that every $(c, o)$-perforated graph of treewidth more than $\tau$ contains either $K_t$ or $K_{t,t}$, or there is a full $(s, o)$-occultation in $G$.

**Proof.** Let $\Sigma = \Sigma(c, o, s, t)$ and $\Lambda = \Lambda(c, o, s, t)$ be as in Theorem 6.1. Let $\Omega = \Omega(c, \Lambda, o, \Sigma, t)$ be as in Theorem 7.1. Let $\tau(c, o, s, t) = \xi(c, o, \Omega, t)$, where $\xi(\cdot, \cdot, \cdot, \cdot)$ is as in Corollary 2.6. Let $G$ be a $(c, o)$-perforated graph of treewidth more than $\tau$. Assume that $G$ contains neither $K_t$ nor $K_{t,t}$. By Corollary 2.6, $G$ contains a strong $\Omega$-block. Therefore, by Theorem 7.1, there exists a $\Sigma$-$\Lambda$-constellation in $G$. But now by Theorem 6.1, $G$ contains a full $(s, o)$-occultation, as desired. ■

9. ACKNOWLEDGEMENT

This work was partly done during the Second 2022 Barbados Graph Theory Workshop at the Bellairs Research Institute of McGill University, in Holetown, Barbados. We thank the organizers for the stimulating circumstances of the event.
